Does the US Navy attract young women who smoke?

Kathleen B Weaver, Susan I Woodruff, Terry L Conway, Christine C Edwards, Shu-Hong Zhu, John P Elder

Abstract
Objective—To assess whether the United States Navy is disproportionately attracting and recruiting female smokers from the civilian sector.

Methods—Standardised comparisons of cigarette use among Navy women recruits and civilian women were conducted with data from a 1996–97 Department of Defense study and the 1994 National Health Interview Survey.

Results—Young Navy women recruits (18–22 years) had significantly higher rates of current and heavy smoking than their civilian counterparts after adjusting for differences in sociodemographic characteristics. Smoking rates among older recruits and civilian women (23–30 years) were not significantly different.

Conclusions—It seems that the Navy attracts young civilian women who already smoke, many of whom smoke heavily.

Keywords: smoking; military; women; tobacco use

The civilian population has seen dramatic decreases in smoking rates in the past 30 years.1,2 Although this decreasing trend has also been evident in the United States military services, smoking rates remain higher among military personnel than among civilians.3,4 Tobacco use is of particular concern to the United States Navy as it is estimated that 35% of Navy personnel is smokers compared with 25% of civilians.1,4 Studies in the 1980s suggested that the military services were creating smokers rather than attracting them, and that military policies and programmes at the time had not been effective in reducing smoking.5,6 The present study considers the attracting part of the creating versus attracting question and focuses on women just entering the United States Navy. No studies to date have been conducted that focus exclusively on military women, and no studies have compared smoking rates among new military recruits and civilians. This paper reports the results of standardised comparisons of cigarette use among US Navy women recruits and their counterparts in the general population. By conducting standardised comparisons, the question of whether the Navy recruits female smokers can be answered more definitively.

Methods

DATA SOURCES
Navy women recruits
This study was part of a larger project sponsored by the Department of Defense to assess the long term effectiveness of two smoking relapse prevention strategies for Navy women.8 Data for Navy women recruits were taken from baseline surveys on tobacco use of all women entering basic training at the United States Navy Recruit Training Command at Great Lakes, Illinois during March 1996 to March 1997. Sociodemographic data were extracted from the computerised Navy enlisted master record (EMR). The record is maintained by the Bureau of Naval Personnel and is used in processing personnel information for all active duty Navy enlisted members.

Of the 5894 Navy women recruits eligible for participation in the study, a total of 5503 (93%) completed a baseline survey. Baseline surveys were matched with sociodemographic data from the enlisted master record by social security number. Twenty four surveys could not be matched. Also, women who were aged 17 on entry into the recruit training (n=325) were excluded from the present analysis due to incomparability with the female civilian population data. Women older than 30 were excluded because of low numbers (n=73). Thus, 5081 surveys (92% of the original surveys) were available for analysis.

Civilian women
Civilian data were extracted from the 1994 National Health Interview Survey, which collects information related to health on a yearly basis through face to face interviews with a sample from the civilian non-institutionalised population residing in the United States. The Year 2000 Objectives Supplement to the National Health Interview Survey was administered to one adult person per family in half of the households in the 1994 sample, and contains questions about tobacco use. A basic weighting was applied which reflects the probability of selection and household non-response, resulting in national estimates of
Smoking among Navy women recruits

Because there were few women recruits in their mid to late 20s, it was not possible to look at the context of the military recruit population. Women in their early 20s, and what would be considered relatively older women in the context of the military recruit population. Because there were few women recruits in their mid to late 20s, it was not possible to look at finer age groupings.

Civilian estimates have been standardised to the Navy distribution of education and race or ethnicity. Civilian data source: 1994 National Health Interview Survey.
administration: the Navy recruit data were collected with self report questionnaires whereas the civilian data were collected in face to face interviews. These differences suggest caution in drawing conclusions from the present study.

Our results from the present study indicate that the Navy is dealing with a population of women who have high smoking rates from the outset of military service. Why the Navy may attract young smokers is not clear. Certain personality factors (sensation seeking, risk taking, rebelliousness, confidence) may play a part. There may be geographical differences such that women who come from regions with high smoking rates may join the Navy in disproportionate numbers. Unmeasured peer and parental factors—for example, veteran status of father—also may influence a young woman to smoke and to choose to join the Navy. Whatever the explanatory factors, however, this finding underscores the need for intensified programmes directed towards stopping smoking during the recruit training period. Perhaps more importantly, there is a need to create expectations among potential recruits that the Navy environment is non-smoker friendly. In 1987, the United States Navy instituted a 24 hour smoking ban during the entire 8 week period of recruit training, and in 1994 the Navy became a smoke free workplace. These are important steps toward changing the Navy environment, which has historically tolerated (and perhaps promoted) smoking. However, more interventions are needed to change other aspects of Navy culture that may foster cigarette use. The military services have a unique opportunity to make a positive impact by reducing cigarette use among its recruits and personnel. Most people who enter military service return to the civilian sector after a relatively brief period of service. Thus, decreasing smoking rates among service personnel would reduce health related costs not only for the military service, but ultimately for the civilian sector as well.

This research was supported by the Department of Defense (DoD), Defense Women’s Health Research Program (DAMD17–95–5075), and by the augmentation awards science and engineering research training (AASERT) grant No DAAH04–96–0116. We gratefully acknowledge Drs Stephen Bender and Richard Hough for their critique of earlier drafts of this manuscript.
