Objectives To determine the relationship between exposure to hard-metal dusts and lung cancer mortality. This international cohort study is coordinated by the University of Pittsburgh and funded by the International Tungsten Industry Association (Marsh *et al* 2013, EPICOH abstract). The German component comprises three Kennametal manufacturing sites in North Rhine-Westphalia and Bavaria.

Methods We enrolled all current and former workers at two Bavarian sites (start of production 1960 and 1971 respectively). At the largest plant in North Rhine-Westphalia (start of production 1926) we will enrol all blue-collar workers who were employed for at least 6 months. We will collect and analyse measurement data, work history, and medical information like smoking and urine data. We will apply an electronic data collection system to protect personal data. To investigate total and cause-specific mortality for the period 1980–2011, we aim to determine each subject's vital status and, if applicable, cause of death. External comparisons (SMRs) to the German population and state populations will be performed. Cox models will be used for internal analyses.

Results Our preliminary estimates of the numbers of participants at the two Bavarian plants are 2,711 and 1,577. At the North Rhine-Westphalian plant we have enrolled 3,700 workers (less than half of the overall workforce). Some current workers refused to be enrolled in the study. 3.7% of 676 and 0.2% of 417 at Bavarian plants and 0.9% of 637 at North Rhine-Westphalian plant. Basic data of these workers will be documented.

Conclusions The data collection process in North Rhine-Westphalia was restricted due to the large number of paper files. Otherwise it would not be feasible to meet the budget and time schedule of the international pooling project. Vital status and cause of death tracing are challenging in Germany. We will try to optimise procedures in cooperation with the responsible institutions.

59 AN INTERNATIONAL HISTORICAL COHORT STUDY OF WORKERS IN THE HARD-METAL INDUSTRY - AUSTRIAN COMPONENT

10.1136/oemed-2013-101717.59

Objectives Researchers at the University of Pittsburgh and the University of Illinois at Chicago are coordinating an international historical cohort study of workers in the hard-metal industry. Funding is provided in part by the International Tungsten Industry Association. From Austria they approached a large industrial plant in Reutte, Tyrol, and the Institute of Environmental Health at the Medical University of Vienna to coordinate the Austrian part of the study that is financially supported by the national workers insurance company.

Methods As a first result of the cooperation between Reutte and Vienna a cross-sectional study was designed based on a questionnaire directed to all present workers and to past workers with still valid addresses. This questionnaire served two purposes: (1) to announce the aim of the cohort study and (2) to obtain more

detailed data on smoking history and general health history than is available in the company records.

Results In spite of repeated advertising of the questionnaire by the Reutte management only approximately 10% of all addressees (233 persons in total) responded. Active workers were over-represented while only 78 (mostly only recently) retired workers completed the questionnaire. Also, current white collar (office) workers were overrepresented (58 persons).

Conclusions Although a respiratory disease or hypertension were each reported by about 10% of respondents the subjective health status was generally good. Better health was reported by office workers while working in departments with the highest dust exposure was not associated with poorer health. Increasing age did not consistently lead to higher symptom rates while smokers reported poorer health not only for respiratory but also for rheumatic and psychiatric symptoms.

We will also report on the progress of our ongoing work on the international epidemiology study.

60 CANCER MORBIDITY OF LEAD EXPOSED WORKERS IN KOREA

10.1136/oemed-2013-101717.60

Objectives To compare cancer patterns in lead exposed workers with the Korean general population, and to explore the relationship between cancer and lead exposure in an occupational setting.

Methods Using from the Korean annual medical surveillance for exposure to lead, a cohort comprising 75,184 lead exposed workers working between January 1st, 2000 and December 31st, 2004 was compiled. This cohort was merged with the Korea National Central Cancer Registry (KNCCR) in order to evaluate the cancer morbidity for these workers between 2000 and 2008.

Results There were 793 cases cancer and, the incidence of stomach cancer (SIR 1.17, 95% CI = 1.01–1.36) was found to be elevated in lead chromate workers. Excesses were observed for kidney (2.15.1.19–3.88) and bladder cancers (2.29.1.149–4.58) in lead exposed workers ≥20 years of job duration, kidney cancer (2.25.1.21–4.18) in workers with ≥10 ug/dl of blood lead level and lung cancer in female workers with ≥10 ug/dl blood lead level.

Conclusions Our study showed excess of lung cancer in female workers, stomach cancer in lead chromate exposed workers and a possible dose-response relationship between kidney cancers and lead exposure.

61 AN INTERNATIONAL HISTORICAL COHORT STUDY OF SWEDISH WORKERS IN THE HARD-METAL INDUSTRY

¹B T Westberg, ²Svartengren, ³Marsh, ³Buchanich, ⁴Kennedy, ⁴Esmen. ¹Örebro, Sweden; ²Karolinska Institute, Stockholm, Sweden; ³University of Pittsburgh, Pittsburgh, United States of America; ⁴University of Chicago, Chicago, United States of America

In 2006, IARC found limited evidence in humans and sufficient evidence in animals that tungsten carbide (WC) with cobalt binder (WCCo) acted as a lung carcinogen (Group 2A). A Swedish historical cohort study was established as part of the international cohort. Three Swedish sites are included,

contributing with 3000 persons and 200 exposure measurements, 7000 persons and 1000 exposure measurements, 7000 persons and 500 exposure measurements, respectively. From the employment records, individual personal id-numbers, date of birth, sex, first and last date of job specific employment periods are extracted. The cohort will be linked to our national Causes of Death register. Cause of death will be established according to ICD 6–10 and compared to national and if possible regional registers. We will establish a measurement database and a site questionnaire for each company. In our analysis we will investigate the total and cause-specific mortality experience of current and former workers as compared to corresponding national and regional populations and internally-derived control groups, with adjustment for potential confounding factors and focus on lung cancer; characterise the past and current working environment of subjects relative to work area, job title/function and potential for exposure to WCCo, as well as the component exposures: tungsten, tungsten carbide (without cobalt), carbon black, and cobalt; and determine the relationship between level and duration of exposures and lung cancer mortality with adjustment for potential co-exposures, including information obtained on tobacco smoking habits via a nested case-control study.

The epidemiological and exposure assessment components of the study are coordinated by the University of Pittsburgh and the University of Illinois at Chicago, respectively. The study is funded by the International Tungsten Industry Association. Progress in the Swedish studies will be reported separately by us.

62 OCCUPATIONAL EXPOSURE TO AROMATIC AMINES AND POLYCYCLIC AROMATIC HYDROCARBONS AND BLADDER CANCER: RESULTS FROM THE EPIC COHORT

¹K G Gawrych, ¹Pesch, ¹Rabstein, ¹Weiss, ¹Casjens, ¹Rihs, ¹Angerer, ²Bueno-de-Mesquita, ²Ros, ³Kaaks, ³Chang-Claude, ⁴Tjønneland, ¹Brüning, ⁵Vineis. ¹Institute for Prevention and Occupational Medicine of the DGVV (IPA), Bochum, Germany; ²National Institute of Public Health and the Environment (RIVM), Bilthoven, The Netherlands; ³German Cancer Research Center, Heidelberg, Germany; ⁴Danish Cancer Society Research Centre, Copenhagen, Denmark; ⁵Imperial College, London, United Kingdom

10.1136/oemed-2013-101717.62

Objectives Exposure to aromatic amines (AA) has been strongly linked to bladder cancer. Also polycyclic aromatic hydrocarbons (PAH) have been associated with bladder cancer. Here we investigate the bladder cancer risk of occupational exposure to AA and PAH using a large prospective cohort in European populations.

Methods We analysed the bladder cancer risk of exposure to AA and PAH in 754 cases and 833 controls nested in the European Prospective Investigation into Cancer and Nutrition (EPIC) cohort. A semi-quantitative expert rating of the probability and intensity of exposure to AA and PAH was performed for 52 occupations known to entail a cancer risk. For each occupation, we multiplied probability (0 = none, 1 = low, 2 = medium, 3 = high) and intensity (0 = none, 1 = low, 2 = medium, 3 = high) of exposure according to an approach for the association with lung cancer. We categorised the subject's sum of scores over all at-risk occupations as low, medium, or high using the tertiles of the distribution in exposed controls. Odds ratios (ORs) with 95% confidence intervals (CI) were estimated with unconditional logistic regression adjusted for the matching factors and smoking.

Results High occupational exposure to AA and PAH were associated with an estimate of the relative bladder cancer risk of 1.37 (95% CI 1.02 to 1.84) and 1.50 (95% CI 1.09 to 2.05), respectively. We further observed an OR of 1.53 (95% CI 1.03 to 2.28) for ever being exposed to dyestuffs. Ever working in transportation and welding was associated with an increased bladder cancer risk in men that became non-significant after controlling for multiple testing. Smoking and PAH exposure yielded a joint effect of 3.48 (95% CI 2.51 to 4.84).

Conclusions We were able to confirm the bladder cancer risk associated with aromatic amines and dyestuffs in this large population-based cohort among Europeans. These results provide further evidence that occupational exposure to PAH could entail a bladder cancer risk.

63 ASBESTOS LUNG BURDEN AND MESOTHELIOMA RISK DUE TO PAST AND CURRENT OCCUPATIONAL AND ENVIRONMENTAL EXPOSURE CONDITIONS IN GREAT BRITAIN

¹Aj Darnton, ²Peto, ²Gilham, ²Rake, ¹Darnton, ¹Hodgson, ³Burdett. ¹Health and Safety Executive, Bootle, United Kingdom; ²London School of Hygiene and Tropical Medicine, London, United Kingdom; ³Health and Safety Laboratory, Buxton, United Kingdom

10.1136/oemed-2013-101717.63

Objectives To characterise the relationship between mesothelioma risk and asbestos lung burden in Great Britain. To identify the asbestos lung burdens due to current or recent occupational and environmental asbestos exposures, and estimate consequent mesothelioma risks.

Methods Lung tissue and lifetime occupational histories were obtained from 136 mesotheliomas, 263 lung cancers and a random sample of 130 individuals from the British population obtained from those having surgery for pneumothorax. Asbestos lung burdens by fibre type were estimated by Transmission Electron Microscopy. Odds ratios for mesothelioma were estimated for asbestos lung burden categories by logistic regression using lung cancers as controls; mesothelioma risk was then modelled by adjusting for asbestos-related lung cancer risk among controls. Changes in mesothelioma risk arising from occupational and environmental exposures in the past and more recently were estimated from asbestos lung burdens of pneumothorax patients by period of birth.

Results A linear relationship between mesothelioma risk and lung burden was seen up to 0.5 million fibres per dry gram of lung (mfpg), and a burden of 0.1 mfpg was associated with a lifetime mesothelioma risk of 1.4%. Mean asbestos lung burdens for mesothelioma, lung cancer and pneumothorax cases born <1965 were positively correlated with the mesothelioma ORs for job categories from previous analyses, with highest burdens associated with construction jobs. Across all jobs, mean lung burdens were highest for mesothelioma (0.223 mfpg), followed by lung cancer (0.060), pneumothorax cases born <1965 (0.045) and finally pneumothorax cases born more recently (0.004).

Conclusions The average lifetime risk of mesothelioma in those born since 1965 is an order of magnitude lower than for those born in earlier decades. Lung burden analyses from a larger sample of pneumothorax patients born since 1965 are needed to more precisely identify recent exposure circumstances that contribute to their residual mesothelioma risk.
