From the Istituto di Radiologia dell'Università Cattolica del S Cuore,¹ and the Istituto di Medicina del Lavoro dell'Università Cattolica del S Cuore,² Roma, Italy

ABSTRACT Five patients exposed to vinyl chloride were studied by hand angiography and other non-invasive methods, including photoplethysmography, reography, and thermography. Raynaud's phenomenon was present in all five subjects, while acro-osteolysis affected only one. Organic vascular lesions, such as narrowing, segmentary occlusions of digital arteries and bridge collaterals, were found in angiographic studies. Only one patient did not show clear segmentary occlusions, but his vessels were crooked and diffusely narrowed. Angiographic results appear to correlate well with the changes shown by non-invasive techniques.

Vinyl chloride causes a complex syndrome, which may include typical Raynaud's phenomenon. The impairment of vascular system function in vinyl chloride disease has been studied in a small group of subjects by means of plethysmography,¹ thermography,² or angiography.^{3,4}

We were unable to find any published study of all these vascular parameters in the same group of patients.

Materials and methods

Of 30 workers having vinyl chloride disease, five who complained of severe Raynaud's phenomenon were selected for detailed study. The mean age was 46 years (range 31-56); mean working age was 12.6 years (range 5-22). Three worked in a vinyl chloride-polyvinyl chloride polymerisation factory as autoclave cleaners; the other two worked inside polyvinyl resin silos (bunker workers) in the same factory.

The severity of their Raynaud's phenomenon was evaluated by a traumatic vasospastic disease index⁵: in all cases the score ranged from 7 to 10 (that is the highest possible score). All the patients showed pseudoclubbing of the fingers, minimal skin changes, hyperidrosis, and paresthesiae. Only one subject had bilateral acro-osteolysis of the index finger; he also had scleroderma-like skin changes.

Each patient underwent digital photoplethysmography,⁶ repeated after cold testing⁷ antebrachial and digital reography,⁸ static and dynamic hand

thermography,⁹ and angiography.

Hand angiograms were performed during general anaesthesia. Thirty ml of iodide contrast medium (Urografin 76%) were injected, at 6 ml/s, in the brachial artery on each side; two x-ray films a second for the first five seconds, and one x-ray film a second for the next three seconds were obtained.

A short, deep general anaesthesia¹⁰ was necessary to complete filling of the digital arteries. We used halothane, a vasodilator anaesthetic, to eliminate painful vasospasm after contrast medium injection¹¹; such arterial spasms may mask underlying occlusive disease in patients with Raynaud's phenomenon when the examination is performed under local anaesthesia.¹² In only one patient was the arteriogram performed firstly under local anaesthesia and secondly under general anaesthesia.

All the investigations were carried out in a thermostatically controlled room (21°C).

Results

In the forearms the amplitude of the reogram was reduced in two cases in the basal state; some morphological changes of the descending segment of the spigmic wave suggested basal vasospasm.

At the fingers during rest four cases showed spontaneous changes of the vascular tone; curves with a wide base and hyperdicrotism, or flattened curves with quickly ascending pulse segment and flatly continuing descending segment, with fairly regular, small waves (saw-waves).

Photoplethysmography showed appreciably flattened curves, with quickly ascending and slowly

descending pulse segments, indicative of a constriction in the arterial system, or "integrated" shape of pulse curves, rounded toward the top, with no dicrotic wave, that indicate the presence of occlusions in the smaller arterial trunks, which are compensated through large-calibre collaterals.

Cold testing evidenced alterations of vascular reactivity ("silent" curves, subsequent appearing of integrated pulse, late pulse recovery).

In all cases thermography showed a non-homogeneous distribution of the longitudinal thermal gradient (LTG), and in several cases abnormal thermographic patterns, ranging in basal conditions from slight hypothermia to clear thermic amputation of some fingers. After cold testing, symmetric amputation affected all the hand up to the metacarpus.

In association with the above findings we found, by arteriography, a generalised narrowing, ranging from scattered stenosis of the vascular lumina in "arteriae digitales propriae," to their complete occlusion. We did not find reduction in size or absence of filling of the palmar arches.⁴ Only in one patient (fig 1) were we unable to observe an obstructive arterial disease; however, the common and arteriae digitales propriae were particularly crooked and irregularly narrowed. A variable degree of crooking was observed also in the remaining cases (figs 2 and 3).

In four subjects we observed complete segmental occlusion of arteriae digitales propriae, with distal

revascularisation by means of bridge collaterals.

The development of numerous collaterals and vascular bridges may often determine zones of pseudohypervascularity.

Discussion

Conventional hand angiography and its variations such as pharmaco and cryodynamic angiography, have been widely used in diagnosing Raynaud's syndrome, both systemic¹²⁻¹⁴ or occupational.^{3 4 15-17}

Interpretation of the angiograms often proves difficult, since many arteries do not conform to a single anatomical pattern.^{18 19} Moreover, most of the cases reported have been studied by different methods and techniques.^{12 14 20}

According to published reports it is not possible to attribute any definite pathological importance to variations in the big vessels or palmar arches in respect of diameter or arrangement.

In the lone case we examined under local anaesthesia we observed a very poor arteriogram. We have considered the evidence of filiform vessels and the complete absence of filling of all the arteries that stream out of the palmar arches in angiograms performed without anaesthesia as a physiological or parapsychological response to contrast medium injection; the degree of correlation with the severity of the Raynaud's phenomenon is poor. We must remember, however, that the early symptoms of Raynaud's phenomenon are vascular hypertonia and

hyperreactivity with vasospasm precipitated by many stress factors (cold, noise, pain, and so on).

We confirm the signs of organic obstructive disease of the little arteries in subjects affected by vinyl chloride disease—already reported by Lange *et al*³—and corresponding to histopathological lesions shown by skin biopsy to consist of uneven endothelial thickening, and thickening of the media of dermal arterioles, with inflammatory infiltrates, predominantly perivascular (lymphocytosis, few histiocytes).⁴

Conclusions

We found a substantial correlation between the results obtained by non-invasive methods and by angiography. We cannot, however, exclude the possibility that a study of a larger number of patients may show discrepancies among reo-plethysmographic and thermographic tests and angio-

graphy. In fact, many patients with classical occlusive disease can be found to have plethysmograms in the normal range, because the plethysmogram tends toward normality when the arteries are able to deliver a substantial amount of blood to the distal phalanges.¹³ For this reason, plethysmography may underestimate the anatomical extent of disease. On the other hand, some anatomical alterations angiographically shown in the presence of Raynaud's disease may be lacking haemodynamic value.²¹

Therefore, we consider angiography to be a useful adjunct to the diagnosis of vinyl chloride disease. It may show organic vascular lesions before the appearance of lytic bone lesions, and may allow early diagnosis; it may discriminate between organic and spastic lesions, and thus be a good indicator of prognosis¹⁴; it may be of some value in assessing the prognosis in acro-osteolysis, because subjects with a better collateral vascular system could improve more

Fig 3 Arteriography of both hands; detail of (a) right finger and (b) second left one. As well as acro-osteolysis of distal phalanges, occlusion of proper digital artery and revascularisation of distal network by bridge collaterals (arrow), distal arteries appear tortuous, narrowed, and apparently increased in number. Pseudoclubbing is present.

quickly.

Pharmacocryodynamic angiography may help to evaluate the response to vasodilator drugs, so helping to choose and assess the treatment. Finally, angiography may provide documentary evidence of the organic lesions in the peripheral circulation for medicolegal purposes. Angiography must be limited to doubtful cases with sufficient risk exposure and must be performed in hospital.
