Fatigue among working people: validity of a questionnaire measure

Anna J H M Beurskens, Ute Bültmann, IJmert Kant, Jan H M M Ver Coulen, Gijs Bleijenberg, Gerard M H Swaen

Abstract

Objectives—To evaluate the validity of the checklist individual strength questionnaire (CIS) in the working population. This 20 item self reported questionnaire has often been used in patients with chronic fatigue. To date, no research has focused on the validity of the CIS in occupational groups.

Methods—To evaluate the discriminant validity the CIS was filled out by five groups of employees with expected differences in fatigue. The convergent validity was evaluated by comparing the results of the CIS with the results of three related measures: measured unidimensional fatigue, burnout, and need for recovery.

Results—The CIS was able to discriminate between fatigued and non-fatigued employees in occupational groups. The expected agreement between the results of the CIS and related measures was confirmed.

Conclusions—The CIS seems to be an appropriate instrument for measuring fatigue in the working population.

Keywords: fatigue; occupational groups; measurement

Fatigue at work is a normal everyday experience. However, in the case of severe fatigue it may affect the person's performance in the occupational as well as the home setting. Moreover, severe long term fatigue may lead to sick leave and work disability.

In The Netherlands about one in every three recipients of work disability benefit is classified as occupationally disabled on mental grounds. They have an “exogenous reaction”; which is the official diagnosis that includes chronic job stress and burnout—that is, a mental state closely related to mental fatigue.

In 1996 a large scale national concerted research action on fatigue at work was initiated in The Netherlands. This multidisciplinary research programme includes psychological and medical research and is supported by grants from The Netherlands Organisation for Scientific Research (NWO), universities, occupational health services, private research institutes, trade unions, and business.

Within the research programme fatigue is defined as: “The change in the psychological control mechanism that regulates task behaviour, resulting from preliminary mental and/or physical efforts which have become bother-some to such an extent that the individual is no longer able to adequately meet the demands that the job requires on his or her mental functioning, or that the individual is able to meet these demands only at the cost of increasing mental effort and the mounting of psychic resistance”.

We see fatigue, in line with Lewis and Wessely, as a subjective sensation with emotional, behavioural, and cognitive components. There is an essential difference between acute fatigue and long term fatigue. Acute fatigue is characterised by reversibility, task specificity, and the functional use of compensation mechanisms. Acute fatigue is a normal phenomenon that disappears after a period of rest, when tasks are switched, or when particular strategies are used—for example, working at a slower pace. By contrast, long term fatigue is irreversible, not task specific, and the compensation mechanisms that were useful in reducing acute fatigue are no longer effective.

To gain more insight in the aetiology and prognosis of long term fatigue at work one of the research programmes within the national concerted research action studies is the epidemiology of long term fatigue. A large scale longitudinal prospective cohort study was started in May 1998. The cohort study surveys a heterogeneous population of over 12 000 employees from different companies and organisations. The follow up is 3 years. Data on work related, psychological, social, physical, and behavioural factors, as well as on the health outcomes fatigue, burnout, need for recovery, and sick leave were collected by means of self administered questionnaires and sick leave administrations systems.

Instruments available to assess fatigue can be divided into unidimensional instruments and multidimensional instruments. According to Smets et al the use of unidimensional instruments excludes the possibility of a more complete description of fatigue. The wording of a single question can introduce substantial difference and may emphasise only one dimension of fatigue. Within the cohort study we have chosen a multidimensional assessment of fatigue.

The multidimensional checklist individual strength questionnaire (CIS) was used to measure chronic fatigue (see appendix). The CIS was designed to measure several aspects of fatigue which is in line with our definition of fatigue. It consists of four dimensions: the subjective experience of fatigue and reduction in motivation, reduction in activity, and reduction in concentration. The CIS was

*Scored on a 7 point scale: lowest education is primary school (1), highest education is university (7).

The internal consistency of the CIS seemed to be good: Chronbach's α for the total CIS was 0.90 and for the scales the α ranged from 0.83 to 0.92. The CIS was able to discriminate between patients with chronic fatigue syndrome, patients with multiple sclerosis, and healthy controls and the convergent validity was also satisfying.

There is, however, no work to date that focuses on the validity of the CIS in the working population. For that reason, a validity study was conducted. The aim of this study was to evaluate the ability of the multidimensional CIS in classifying employees according to their level of fatigue. The CIS was filled out by five groups of employees with expected differences in fatigue: two groups of healthy employees, two groups of employees with a somatic reason for fatigue, and one group with a mental reason for fatigue. Also, the scores on the CIS in the working groups were compared with a reference group of patients with chronic fatigue syndrome. Our hypotheses were that the employees with a mental reason for fatigue and the employees with a somatic reason for fatigue would score higher on all dimensions of the CIS than the healthy employees. The convergent validity of the CIS was evaluated by comparing the results of the CIS with the results of three related measures: fatigue measured on a unidimensional five point Likert scale, burnout, and need for recovery.

Burnout is a mental state which can be regarded as an extreme expression of long term fatigue. The employees’ need for recovery can be considered as a mediating or moderating characteristic in the aetiology of fatigue.

Subjects and methods

STUDY POPULATION
To evaluate the ability of the CIS to discriminate between fatigued and non-fatigued subjects we formed five sets of employees with expected differences in fatigue: two sets of healthy employees, two sets of employees with a somatic reason for fatigue, and one set with a mental reason for fatigue. All employees were employed for ≥20 hours a week.

The first group of employees consisted of 37 healthy white collar workers with mental work, mostly working at a university. The second group consisted of 38 healthy blue collar workers with industrial work. These employees performed heavy, dirty work in an iron foundry. We asked the healthy employees to fill out the questionnaire. The third group compared 38 patients who had had an operation for low back pain hernia. The physiotherapists in attendance asked the patients to fill out the questionnaire 5–7 days after the operation. The fourth group of employees were pregnant women (n=47). The median duration of the pregnancy was 27 weeks. Their midwives asked if they wanted to participate in the study. The third and fourth groups had a somatic reason for fatigue. Company doctors and insurance doctors selected the fifth group with a mental reason for fatigue. We asked the doctors to select employees with a mental reason for fatigue and to exclude employees with psychiatric illness. The doctors asked eligible patients to fill out the questionnaire. In total, 59 employees with a mental reason for fatigue returned the questionnaire. For privacy reasons we do not know the exact diagnosis of these subjects.

Table 1 shows the characteristics of the five groups of employees. The groups were different on some characteristics but most differences were related to the selection of the groups—for example, sex in the group of pregnant women. However, the education level in the fifth group was high. This can be explained by the fact that the employees in this group were mainly white collar workers.

QUESTIONNAIRE
All 219 employees received a self administered questionnaire which contained questions about demographic factors, fatigue, burnout, need for recovery, and sick leave.

The CIS was used to measure fatigue, it consists of 20 statements for which the person has to indicate on a 7 point scale to what extent the particular statement applies to him or her. The statements refer to aspects of fatigue experienced during the previous 2 weeks. The number of items per dimension varies. The dimension “subjective fatigue” has eight items—for example, I feel tired—“reduction in motivation” four items—for example, I feel no desire to do anything—“reduction in activity” three items—for example, I don’t do much during the day—and reduction in concentration five items—for example, My thoughts easily wander. Also, by adding the four dimensions a CIS total score can be calculated. Higher...
scores indicate a higher degree of fatigue, more concentration problems, reduced motivation, and less activity.

Fatigue was also measured on a unidimensional five-point Likert scale. Employees were asked to rate their perceived fatigue during the previous 2 weeks, ranging from “very often” to “rarely or never”.

Burnout was measured with the Maslach burnout inventory—general survey (MBI-GS). The Maslach burnout inventory was originally developed to measure burnout in human service providers.12 Recently, a measure of burnout was developed which can be used also in other occupations the MBI-GS.12,15 This MBI-GS has three subscales that parallel the MBI: exhaustion, cynicism, and professional efficacy. The exhaustion items are generic, without the MBI’s emphasis on emotions and without direct reference to service recipients. The items include references to both emotional and physical fatigue. The items of the subscale cynicism reflect indifference or a distant attitude toward work itself. A strong degree of exhaustion, cynicism, and a low degree of professional efficacy are indicative for the syndrome burnout.13

The need for recovery was measured with six items from a validated Dutch questionnaire about psychosocial job demands on job stress.13 The questions asked about the situation at the end of a working day—for example, if the employees still feel fresh after supper or if they are able to relax only on a second day off.

ANALYSES

All data analyses were done with SPSS statistical software.16 To gain insight in the discriminant validity, differences among the five groups of employees for the four dimensions of the CIS were calculated with univariate analyses of variance (ANOVA).16

Table 1 shows that the education level of the employees in the group with a mental reason for fatigue was high. We corrected for the effect of education, age, and sex with ANCOVA. However, the adjustments were not significantly different and only slightly changed the CIS scores.

MBI-GS=Maslach burnout inventory—general survey.
The corresponding correlation coefficient was 0.62.

**CONVERGENT VALIDITY**

Table 3 shows the results of the MBI-GS, unidimensional fatigue, and need for recovery in the five groups. Except for the scales cynicism and professional efficacy of the MBI-GS, the scores in the mental group were higher than the scores in the other groups. For the scale exhaustion of the MBI-GS and for need for recovery the differences between the mental group and all the other groups were significant. These results correspond to a large extent to the discriminant results of the CIS. Figure 2 shows the scatterplot of CIS total and the sub-scale exhaustion of the MBI-GS in the group of employees with a mental reason for fatigue. The corresponding correlation coefficient was 0.62.

**Discussion**

The aim of this study was to evaluate the ability of the multidimensional CIS to classify study subjects according to their level of fatigue. It seemed that the CIS was able to discriminate adequately between fatigued and non-fatigued employees in occupational groups. The results of the CIS were comparable with the results of three related measures: fatigue measured on a unidimensional five point Likert scale, the scale exhaustion of the MBI-GS, and need for recovery. Also, the correlation between CIS total and the scale exhaustion of the MBI-GS in the mental group was in the expected direction and high. No gold standard exists for fatigue. Therefore, we will never be able to prove the validity of instruments measuring fatigue. In the absence of a gold standard, direct comparisons of methods of measuring fatigue with related and existing measures are needed. In this study we compared the discriminant ability of the CIS with discriminant abilities of related measures.

It was noticeable that the group of employees with a mental reason for fatigue scored systematically higher on all dimensions of the CIS than the groups of employees with a somatic reason for fatigue. We do not know how severe the mental reason was or if these subjects also had somatic complaints. However, we noted that the scores of the patients with the chronic fatigue syndrome were substantially higher for most of the dimensions than the scores of the employees with a mental reason for fatigue.

The groups of employees with expected differences in fatigue were chosen carefully. The CIS was able to discriminate between these groups. If the CIS had not been able to discriminate between these selective groups then, we anticipated, it would certainly not be able to discriminate between less different groups.

According to Kirshner and Guyatt11 questionnaires can be used for three purposes: (a) discriminating among subjects, (b) predicting prognosis, and (c) evaluating change over time. Questionnaires with different purposes require different measurement properties.17 In this study we found evidence for a satisfactory discriminating ability of the CIS. In other studies the CIS seemed to be able to measure change in fatigue scores in groups as well as in individual workers in randomised controlled trials and over a longer period.9 10

We conclude that the CIS is able to discriminate between groups with expected differences in fatigue. The CIS seems to be an appropriate instrument for measuring fatigue in the working population.

Instruction:
On the next page you find 20 statements. With these statements we wish to get an impression of how you have felt during the past two weeks. For example:

I feel relaxed

If you feel that this statement is not true at all, place a cross in the right box; like this:

I feel relaxed

yes, that is true X no, that is not true

If you feel that this statement is not true at all, place a cross in the box that is most in accordance with how you have felt.

For example, if you feel relaxed, but not very relaxed, place a cross in one of the boxes close to “yes, that is true”: like this:

I feel relaxed

yes, that is true X no, that is not true

Do not skip any statement and place only one cross for each statement.

1. I feel tired yes, that is true no, that is not true
2. I feel very active yes, that is true no, that is not true
3. Thinking requires effort yes, that is true no, that is not true
4. Physically I feel exhausted yes, that is true no, that is not true
5. I feel like doing all kinds of nice things yes, that is true no, that is not true
6. I feel fit yes, that is true no, that is not true
7. I do quite a lot within a day yes, that is true no, that is not true
8. When I am doing something, I can concentrate quite well yes, that is true no, that is not true
9. I feel weak yes, that is true no, that is not true
10. I don’t do much during the day yes, that is true no, that is not true
11. I can concentrate well yes, that is true no, that is not true
12. I feel rested yes, that is true no, that is not true
13. I have trouble concentrating yes, that is true no, that is not true
14. Physically I feel I am in a bad condition yes, that is true no, that is not true
15. I am full of plans yes, that is true no, that is not true
16. I get tired very quickly yes, that is true no, that is not true
17. I have a low output yes, that is true no, that is not true
18. I feel no desire to do anything yes, that is true no, that is not true
19. My thoughts easily wander yes, that is true no, that is not true
20. Physically I feel in a good shape yes, that is true no, that is not true

SCORING CIS20R
For the items: 2, 5, 6, 7, 11, 15, 18, 20 is the scoring as follows:

yes, that is true 1 2 3 4 5 6 7 no, that is not true

For the items: 1, 3, 4, 9, 10, 13, 14, 16, 17, 19 is the scoring as follows:

yes, that is true 7 6 5 4 3 2 1 no, that is not true

Subsequently the four subscales are calculated by summing the respective items:

subscale 1: Subjective feeling of fatigue items 1, 4, 6, 9, 12, 14, 16, 20
subscale 2: Concentration items 3, 8, 11, 13, 19
subscale 3: Motivation items 2, 5, 15, 18
subscale 4: Physical activity items 7, 10, 17
