Cerebral symptoms from mobile telephones

Editor—Disturbing symptoms from the use of mobile telephones are being increasingly reported and have been described by Hocking.1 One of us (RAFC) has also collected a series of such cases but has not published them to date.

Many of these cases are characterised by symptoms of dizziness, disorientation, nausea, headache, and transient confusion. Such symptoms might be expected to arise from unilateral stimulation of the vestibular apparatus. This could occur from the direct action of the radio waves on the endolymph or the hair cells in the semicircular canals or from convection currents set up in the external auditory meatus from the heat of the mobile phone. Most patients complain of a sensation of heating round the ear, often accompanied by reddening of the skin. Blanks et al. have shown that there is significant variability in the precise orientation of the semicircular canals, which may result in a predilection to greater thermal stimulation in some people. Because mobile telephones tend to be used in noisy situations, the user holds the instrument much more tightly to the ear than he does a normal phone.

In our opinion there is good theoretical and clinical evidence to support the hypothesis that some people, perhaps 5% to 8% of mobile phone users, have transient symptoms of vestibular disturbance associated with their use. We think that the hypothesis should be tested experimentally. As the number of people affected will increase as use of mobile phones increases, it is important to confirm our hypothesis experimentally and to find the mechanism underlying vague symptoms of disorientation and to emphasise that these symptoms do not indicate any greater risk of developing brain cancer, whether or not mobile phones are ultimately shown to have any association with cerebral tumours.

The research required is relatively simple and we would suggest that, in the light of widespread public concern, this work should be included in any programme which is proposed to clarify the issues about safety of mobile telephones.

BOOK REVIEWS

If you wish to order, or require further information regarding the book reviewed here, please write or telephone the BMJ Bookshop, PO Box 295, London W1X 9TE. Tel: 020 7383 6244. Fax: 020 7383 6662. Payment can be made by cheque in sterling drawn on a UK bank, or by credit card (MasterCard, VISA, or American Express) stating card number, expiry data, and your full name. (The price and availability are occasionally subject to revision by the Publishers.)

In August 1998 a 2 day workshop was held under the auspices of the United States National Research Council (NRC) to examine the research base on work related musculoskeletal disorders, and this was later followed by some deliberations of the steering committee. The report of the steering committee and the proceedings and scientific papers from the workshop are presented in this monograph.

The NRC workshop, which was attended by leading scientists from the fields of orthopaedic surgery, occupational medicine, public health, and human factors, was supported by the major health insurance industries, and the National Institute of Occupational Safety and Health (NIOSH). In the years since 1990 there has been considerable evidence that musculoskeletal disorders are now a major public health problem, not just in workplaces but also in the wider society. As many as 30% of all new claims in workers’ compensation schemes arise from musculoskeletal conditions. To address this problem a number of major research initiatives have been undertaken, such as those supported by the National Institute for Occupational Safety and Health (NIOSH), the Office of Technology Assessment, or the National Academy of Sciences-National Research Council.

The preface to this book indicates that its intended readership includes practising occupational physicians and nurses, specialists in musculoskeletal disease, family practitioners, and members of the health insurance industry. Whether or not it content fits the stated target. This is not a practical primer, nor a scholarly and dispassionate review of the relation between work and musculoskeletal disease. It is a very honest, brave, and personal view of the author who thinks such diseases arise in the main from illness behaviour and illness labelling.

Their basic tenet is that musculoskeletal symptoms are ubiquitous and generally benign, but can become incapacitating as the patient and the physician seek a medical explanation and supply a diagnostic label. They also seek to dispute much received medical wisdom, the evidential basis of which they dispute. Chapter headings such as “the dangers of the diagnostic process”, “iatrogenic labelling as in the fibromyalgia paralogs”, “the disabled, the dispute” reflect these twin viewpoints, which give rise to passages such as: “...Raynaud’s phenomenon denotes a personality trait; it’s not a disorder”, and headings such as “carpal tunnel syndrome is not a cumulative trauma disorder”. This eclectic book is striking in the enthusiasm with which it embraces the psychosocial model of musculoskeletal disease and disparages the mechanical-biological model. It is well referenced and informative, with critiques that are both energetic and relentless, but ultimately the authors’ stance of unchallenged bias colours the whole book.

This is a pity. Many of the ideas expressed on causation are compatible with widely held views of illness behaviour (although forcibly expressed). There are also interesting and potentially useful chapters on workers’ compensation schemes and coping with arm pain in the workplace.

But lack of balance is not the book’s only shortcoming. Given its title, there are also several surprising omissions. For example,
the clinical chapters (on the neck, back, upper limb, and lower limb) provide little information on putative occupational risk factors and the epidemiological evidence surrounding these. As befits a textbook that reflects the American care model in occupational health, there are passages on therapeutics—such as the side effects of salicylates—and information on homeopathy, osteopathy, and chiropractice; but the bias is towards the clinical rather than the occupational health management of musculoskeletal disorders, and this too was something of a surprise and a disappointment. Fitness for work and its assessment is not considered in a meaningful way.

The question is whether the good outweighs the bad. You pay your money and take your choice: if you want a healthy dose of scepticism, this is the place to look; however, there is a danger you may receive an overdose, and if you prefer a balanced or more dispassionate account you should look elsewhere.

KEITH PALMER

Among the most serious dangers to public health is air pollution. It is at least as important as cancer and vascular disease as a cause of death, illness, and lost human potential, it is a major source of environmental damage, and it seems to be an inescapable companion of industrial progress. In the 19th century we measured a country's power by its production of sulphuric acid, perhaps we should now do so by the acid particles breathed by its citizens? After the very obvious air borne disasters of the 1930s due to fogs in Britain, Mexico, and the USA, there was a rapid legislative and technical response to reduce obvious sources of pollution, and then medical and scientific attention fell away until the growing menace of asthma and other respiratory diseases, coupled with our better ability to detect and measure airborne substances showed that the problems were as serious as ever, even if more subtle in their form and impact.

This book rightly claims to be the first attempt to produce a comprehensive account of the sources, mechanisms, physical behaviour, and health effects of air pollution, and of approaches to its regulation, including forays into economics, trade-offs between risk and benefit, and communication about risk with the public. There are 68 authors from Europe and the Americas, all of whom are making active contributions to understanding this huge area. Considering their research interests, they have been surprisingly well marshalled by the four distinguished editors into writing up date, readable, and informative chapters.

The general approach has been encyclopaedic as the nine major sections cover the history of air pollution, physical meteorology, atmospheric chemistry, the physical geography of air pollution related to its main sources, the measurement of personal exposure, health effects in humans and in laboratory systems, details of major chemical and particulate pollutants, the estimation of health and financial impacts and approaches to regulation including national and international setting of standards for air, and two way communication with the public. The text is accompanied by many clear diagrams and graphs, and several helpful photomicrographs, and every chapter carries many pertinent and recent (to 1998) references.

The strengths of this book are its breadth and clarity, and so its value both as a source of and post-information and communications, and as an entry point into the detailed research literature. I particularly appreciated the information about meteorology, atmospheric chemistry, and surveillance and measuring strategies for the biologist, and the focused accounts of epidemiology and respiratory physiology, defences, and diseases, which should inform the physical scientist about the subtle difficulties of biology. Its weaknesses are those of any synoptic work—the reader must have some background knowledge to understand the depths of the knowledge presented, and the need for broad coverage prevents the inclusion of extensive detail. The balance seemed correct to me in most respects, as the references always pointed to original sources that could be read with appropriate cautions and criticisms in mind. Physicians at any level, public health officials, and sanitary engineers should consult this book regularly. It will be of as much value and interest to regulators, lawyers, and industrial engineers looking into the causes and possible control of air pollution and it will be a major source for any public group wishing to know more of the facts and doing something about the aerial refuse we now breathe.

ANTHONY D DAYAN

Britain has a lengthy and mixed history in the world of toxicology; some industrial and community diseases due to toxic substances have occurred and were first recognised here from the 1st century AD onwards, and our scientists have made seminal contributions to the basic understanding of toxicology. Is this major work to be the epitaph of our achievements, as academic and industrial pressures relentlessly diminish our base of working toxicologists, or is it a further pointer to our understanding of the knowledge and practice of a subject of growing public importance? And, being the second edition of a justifiably successful monograph, how well have advances been included and presentation improved?

The new preface points out the considerable extent of the new material in the book, recognising the speed of progress in molecular toxicology coming from new knowledge in basic sciences, and the wide changes in regulatory approaches to assessing the safety of most products, food, and the environment. As a result, it has grown from two to three volumes, the extensive reference lists have been brought up to date, sometimes with the addition of focused suggestions for additional reading, and the multinational character of the list of authors has been further expanded.

The editors have served their readers well by providing a very extensive survey of the sciences and other factors that underlie toxicology as a discipline applied to the demonstration and understanding of chemical hazards and to practical control of toxic risks in the home, at work, in the clinic, and in the environment. The 116 subjects of the subject index and the 38 pages of the chemical index together lead the enquirer to critical accounts of almost every topic that could be brought into toxicology, including education, studies in man, further developments and the covetously termed "idiopathic environmental intolerances" (multiple chemical sensitivity, and its cousins). There is particular strength in the clarity of the links made with cognitive subgroups, such as phobia, psychological, analytical chemistry and biochemistry, immunology, and veterinary and human medicine. A major feature is the concentration on methods to recognise, study, and assess toxicity, in its many guises, from cell toxicity directly to accounts of good practices in examining substances and circumstances for evidence of toxicity, and how to use that information to evaluate the risks of exposure.

The book is more, much more than a list of techniques and regulations. It is also a major reference source in its own right, providing basic and practical information about the actions, toxicology as a discipline applied to the demonstration and understanding of chemical hazards and to practical control of toxic risks in the home, at work, in the clinic, and in the environment. The 116 subjects of the subject index and the 38 pages of the chemical index together lead the enquirer to critical accounts of almost every topic that could be brought into toxicology, including education, studies in man, further developments and the covetously termed "idiopathic environmental intolerances" (multiple chemical sensitivity, and its cousins).
