CORRESPONDENCE

PBN as a possible bladder carcinogen

In their paper updating a previous investigation of the mortality of workers employed at a factory manufacturing chemicals in North Wales, Sorahan, Hamilton, and Jackson plead for priority to be given for studies on the cancer experience of other working populations exposed to N-phenyl-β-naphthylamine (PBN).

It is, therefore, disappointing that the authors made no reference at all to studies conducted by the British Rubber Manufacturers’ Association (BRMA), and others, on rubber workers employed after 1950. These workers would have been exposed to PBN, and to other antioxidants still in use after the discontinuance (in 1949) of Nonox “S” and similar compounds contaminated by 1-naphthylamine (BNA). This contaminant, and that of N-methyl-N-phenyl-1-naphthylamine (BNA), was found in the factory workforce studied, but on all the evidence presented, in our opinion, it is unjustifiable to ascribe a suspicion of carcinogenicity to PBN, when overall the epidemiological and other evidence available is more reassuring than not.

C A VEYS
University of Keele, School of Postgraduate Medicine, Industrial and Community Health Research Centre, North Staffs Medical Institute, Harthill Road, Stoke On Trent, Staffordshire ST4 7NY, UK

1 Sorahan T, Hamilton L, Jackson JR. A further cohort study of workers employed at a factory manufacturing chemicals for the rubber industry, with special reference to the chemicals 2-mercaptobenzothiazole (MBT), α-toluidine, β-naphthylamine and o-toluidine. Occup Environ Med 1996;53:558–73.

Sorahan and Jackson reply—We agree with Veys that his study of workers exposed to phenyl-β-naphthylamine (PBN) while engaged in the manufacture of rubber tyres indicates that such workers do not experience increased risks of bladder cancer, and that the finding of his study need to be considered along with our own new findings in arriving at any overall evaluation. Our simplest interpretation of the new findings was that “PBN (or a chemical reagent of chemical intermediates) in the production of PBN at this factory in the 1930s or 1940s was a bladder carcinogen”, that other interpretations were possible and that all needed to be “treated with caution”. Our emphasis on the possible role of chemical intermediates matches the concerns of Veys—namely that epidemiological findings relating to workers engaged in the manufacture of a given chemical may be quite different to those pertaining to workers with the same chemical. Clearly, large scale studies relating to both sets of circumstances should assist confident interpretation.

1 Harrison RM, Leung PL, Somerville L, et al. Analysis of incidence of childhood leukaemia in the West Midlands in the age group 0–14 years in the period 1993–7, and therefore non-lymphocytic types accounted for only a very small proportion of childhood leukaemia. The important findings of Harrison et al (for further references) is that living in areas of high car density, means a higher risk of childhood leukaemia, which may be preventable. We think that as benzene is a known cause of non-lymphocytic leukaemia in adults, much more thorough studies in children before we can rule out that benzene is an important factor in childhood leukaemia.

So even if we disagree with Harrison et al about the importance of the risk, we agree that further studies are necessary. They should focus on different types of leukaemia and use much better precision in the estimates of benzene and other possible exposures.

corroboration, and indeed would not be consistent with United Kingdom smoke control laws. The inventory of air pollutant emissions for the conurbation indicates that 99% of benzene emissions to atmosphere arise from road traffic. Our paper gives some indication of the likely gradients between cases at the roadside and those in urban background locations. Although children are also exposed to benzene when travelling in cars, the duration of exposure is relatively short and our earlier paper on personal exposures to aromatic hydrocarbons suggests that this will be a minor contributor to overall exposure. It is exposure in the home and workplace (or in the case of children, in the school) which is dominant. It is likely that other sources of exposure are relatively similar on average for the more exposed and less exposed groups and therefore the main difference relates to the point of residence and the influence of outdoor air on indoor concentrations.

Järvholm and Forsberg cite a Danish study which showed significantly higher front door concentrations of benzene in a city than in rural areas. In the United Kingdom West Midlands the risk of childhood cancer is higher in rural than in urban areas which suggests that benzene exposure is unlikely to be a major factor and that other causal agents such as population mixing may be far more influential. None the less our results do suggest a slight excess of cancers for children living close to major roads and petrol stations and we wholly agree with Järvholm and Forsberg that this merits further investigation.

Prevalence and risk factors for latex allergy: a cross sectional study in a United Kingdom hospital

EDITOR—The recent report by Smedley et al is useful in measuring the prevalence and risk factors for latex allergy within a United Kingdom environment, and providing an up to date review of this problem.

The paper highlights the high frequency of symptoms in healthcare staff but suggests a low frequency of confirmed type I latex allergy. Those who only read the abstract might be misled into considering that the frequency is much lower (two of 372 respondents). The frequency among those tested with specific IgE antibodies was 3% (one of 33) and one person without symptoms was positive on testing (4%; 1/26).

Within the Argyll and Clyde region health surveillance has been performed on staff working in areas with exposure to glutaraldehyde. Such staff also receive advice to protect them from blood and body fluids. A recent audit of the results of health surveillance over the past 3 years identified seven cases of type I latex allergy (confirmed by specific IgE radio allergosorbent test (RAST)) in a workforce of 226 nurses (3% prevalence). The frequency of reported skin symptoms was higher (6% at the last health surveillance) but other cases were also identified (such as rosacea, seborrhoeic eczema, irritant dermatitis, and type IV allergy to colophony, formaldehyde, and rubber accelerators).

The findings confirm a low frequency of type I latex allergy and support the view that highly intensive health surveillance is not justified. One of the seven healthcare workers identified noted an allergic reaction after eating a sandwich bought from the hospital canteen which had been handled by a member of the catering staff who was wearing latex gloves. Healthcare workers with type I latex allergy can be exposed to latex proteins away from their own work area by such actions or from the contact use of powered gloves in other areas. This emphasises the need for an organisational approach to this issue. Organisational action to reduce the incidence of this allergy should have priority including the use of non-powered latex gloves where exposure to blood and body fluids is a risk for those without allergy, the provision of non-latex gloves for those identified with type I allergy and early assessment of those with symptoms related to glove use. Catering staff do not now use latex gloves in the hospital where the reaction reported here occurred.

Prevalence and risk factors for latex allergy

EDITOR—We read with interest the cross sectional study of latex allergy of workers in a United Kingdom hospital. We have also tried to study healthcare workers in a district general hospital and have had problems with the response rate for skin prick testing and also blood taking. We have, however, used standardised and evaluated skin prick test materials from Stallergen (1:200) and the Pharmaceuticals in the UK registry, Central Building, Mickeviciaus str 9, LT-3000 Kaunas, Lithuania.

Epidemiology is still the core discipline in preventive medicine despite recent and important achievements in biology and clinical medicine. This discipline plays a key part in public health and clinical research. This will
BOOK REVIEWS

The first edition of this famous book was published in 1969 and rapidly established itself alongside works by Comroe and Cotes as required reading for respiratory physiologists and especially for anaesthetists. This new edition—the original author having handed the torch to Lumb, maintains the high standards of its predecessors. As the editors have proposed changes in the arrangement of sections of the book have been made. These are most marked in this edition: basic principles, applied physiology, and the physiology of pulmonary disease now being the sections that contain the 539 chapters. The last section is a new venture and contains much new material. To keep the book to about 700 pages Lumb has excised some material that was in the earlier editions. This is recognised by the original author in his foreword. Casual readers will notice few changes—“thou” much is taken, much abides and the quality is undiminished.

The book begins with a chapter, by the original author, on the atmosphere. This is outstanding and should be read by all physiologists. Did you know that half the expected life of this planet has passed? I didn’t and it is a sobering thought. The author makes the point that our atmosphere has dictated our physiology. Current concerns about antioxidants in the diet and their role in protecting the airways against free radical attack are prefigured by the chapters that review details of oxygen radical formation see page 496: the chemistry is complex but elegantly explained. Section 1 continues with accounts of lung structure, elastic forces, resistance to gas flow, the control of breathing; the role of the pneumo- and thence to the matching of ventilation and perfusion. This has always been a difficult chapter and some changes can be recognised. It is still difficult but recent advances in modelling of the use of the MIGET technique have done much to simplify the theory. Discussion of the Riley, Fenn, Cournard model has been reduced—this may be more to anaesthetists than to physicians. This area has provided much with much quiet intellectual amuse- ment (and instruction) at the cost of a few pencils and some reams of paper only! Those proposing to follow a career in respiratory physiology should read the account given in earlier editions of this book. The “applied” sections of earlier editions appealed, I suspect, more to anaesthetists than to physicians. This should no longer be the case. Pregnancy, sleep, air pollution, and smoking for example are all now given chapters of their own: indeed, only one chapter is headed “anaesthesia”. The book now provides an account of most of that which a respiratory physician or anaesthetist should know about pathophysiology. The chapter on acute lung injury is particularly good with an excellent account of the role of cytokines.

The book concludes with five appendices dealing with the maths and physics. The appendix on nomograms and correction charts will appeal to many: the Gordon-Anderson graph on PaO2–FiO2: nomogram remains as does the invaluable PaO2–FiO2–shunt nomogram (much photocopied!).

Reading this book has been a pleasure. It is the best single volume account of pure and applied respiratory physiology now available. At £59.50 it is a bargain—buy it!

R. L. MAYNARD

The structure and functioning of the United States healthcare system is perceived by many as being analogous to an inscrutable labyrinth. Moreover, the medicolegal terrain in which physicians practice in the United States is extraordinarily litigious. Liang’s remarkably well researched, and excellently written, book Health law and policy provides healthcare practitioners with a lucid, detailed road map to avert legal catastrophes in the mine ridden, United States medicolegal landscape.

Although Liang’s book is a superb compendium specifically of United States medicolegal issues and principles, it is noteworthy that the legal systems of the United States and United Kingdom are rooted, similarly, in the soil of judge made, “common” law. As such, Liang’s expert examination of the simply developed body of United States medicolegal case precedents, spawned by the highly active legal system in America, may be of considerable instructive value to healthcare practitioners in the United Kingdom desiring to avoid entanglement in legal traps.

Liang has a trio of doctoral degrees (in medicine, public policy, and law); and earns a living as a professor at an American law school. By virtue of his unusually wide ranging formal educational background, Liang is able to present a clearly and very comprehensive and dissect multidisiplinary, timely issues residing at the interface of law and medicine. The book is configured into four parts, encompassing 16 chapters. An often and effectively used mantra of Liang is to identify a medicolegal concept; and then provide an illustrative case, based on a real life case, followed by a pithy legal discussion of the case illustration. Generally, the numerous cases and accompanying legal discussions brightly illumine the adjoining textual material.

In part I of the book, Liang focuses readers’ attention on traditional areas of concern in the realm of law and medicine, including such topics as informed consent and confidentiality. In part II, Liang works assiduously to sketch the contours of the healthcare insurance structure in the United States. Modern delivery considerations—for example, physician licensure, fraud issues, antitrust and assisted delivery considerations—for example, physician or anesthetist should know about pathophysiology. The chapter on acute lung injury is particularly good with an excellent account of the role of cytokines.

The book concludes with five appendices dealing with the maths and physics. The appendix on nomograms and correction charts will appeal to many: the Gordon-Anderson graph on PaO2–FiO2: nomogram remains as does the invaluable PaO2–FiO2–shunt nomogram (much photocopied!).

Evaluation in occupational health practice, 1st edition
Edited by: EWA MENCKEL, PETER WESTERHOLM. (Pp 235; £40).
ISBN: 0 7506 4303 X.

Evaluation of healthcare systems, with its significant use of qualitative data, has to date received less emphasis in relation to conventional research methods. However, study designs such as randomised control trials are of limited use when occupational health services seek to describe their own practice or are asked to justify programmes to employers, who expect such activities to impact on the functioning of their organisations. The evaluation approach, developed partly in the social sciences, helps provide models for such research questions. Calls for a greater synthesis on such studies have been heard in the BMJ and Occup Environ Med. Menckel and Westerholm's book coherently draws together the conventional study methods and these newer approaches. In doing so the potential researcher is encouraged to seek clarity of thought in the question to be addressed before the study design is selected, to consider the role and expectations of stakeholders, and to consider the wide range of potential outcomes from any occupational health programme.

The evaluation approach requires a knowledge of theory and this book provides a useful introduction that may help occupational health specialists see the workings of their own departments in a new light. The book has a consistent emphasis on occupational health experience and rarely strays into unnecessary theory. The principal weakness is a lack of worked examples on common themes in occupational health practice—for example, management of sickness absence. However, as the authors observe, comparatively few evaluation studies have been published in the occupational health literature and this book will no doubt help correct this situation.

This thought provoking book encourages reflection on the daily practice of occupational health and offers a wide range of approaches that may be adopted to evaluate commonly faced issues. Such approaches may read not only to formal research but also to well informed management decisions on the development and impact of occupational health services. In conclusion this book is worthy of inclusion alongside standard texts of statistical and research methods, but is likely to be of greater use in the day to day management of occupational health services.

PHILIP WYNN

Occupational health: recognising and preventing work related disease and injury, 4th edition

This is the 4th edition of Occupational health: recognising and preventing work related disease and injury, edited, as before, by Levy and Wegman. Four editions—1983, 1988, 1995, and now 2000—say something in itself: there must be out of print there buying it in sufficient numbers for the publishers to countenance the expense of a further edition. There must also be sufficient changes and updates between editions for some people to buy it again for the updates. The questions for the reader of this review must be: Is this a genuine update with additional relevant material to suit the new millennium and is the book worth the price? The short answer, on both counts, is yes.

I have read or scanned all the chapters and I can say that this is a genuine update. Many chapters have been largely rewritten, and where necessary, updated. Some—such as epidemiology—do not require such major revisions as others. The new chapters have become longer in 5 years. New chapters have been added: environmental health, occupational health service, injuries, young workers, older workers, and healthcare workers.

One of the criticisms I had of earlier editions was the book's heavy American bias: to some extent this is still true but less so. The list of contributors is truly international and many are the leading authority on their subject. In some cases—for example, worker compensation—I think the book is still missing a trick by being so United States orientated. The broad concepts of recompensation and the worker are worth spelling out and there is much to be gained reviewing the way different countries approach the issue. There is even now the stance taken by pan national organisations, like the European Union, to harmonise these schemes across national boundaries. What we get is the United States scene by and large.

In other areas the book has not expanded to meet the needs of today. For example, the chapter on shift work is about shift work. Very good it is too but the issue for today is working hours, not just shift work. Much is known and agreed about the health effects of shift work. The new unanswered questions relate to long or irregular hours of work.

Still, these are relatively trivial issues to raise in relation to this splendid book. It is authoritative, well written, and ably edited. It covers the broad gamut of occupational health illness and occupational health practice. It also now has few peers among the middle sized books (is a book of now 842 pages as opposed to 650—middle sized?) Last time around I thought Levy and Wegman (3rd edition) had the edge on Waldron's Occupational Health (3rd edition). The 4th edition of Waldron's book (Waldron and Edging) is not a true update but a supplement to the 3rd edition and retains the very patchy in quality and suffers also from some poor editorial control.

So, Levy and Wegman's 4th edition is clearly out in front. If you do not possess one or even if you do own an earlier edition, there's enough in this new edition to warrant the modest outlay.

PHILIP WYNN

Instant notes in immunology
Edited by: MORTON LIPPMANN. (Pp 987; £96.50).

This is the second edition of Lippmann's well known book on environmental toxicants. Seven new chapters are included bringing the total to 30. Forty one authors make contributions and the book runs to almost 1000 pages. Despite this it is surprisingly slim, due to the use of fine high quality paper, and the book is pleasant to hold and read.

The editor has set out to provide in depth reviews of environmental toxicants: including air pollutants, dioxins, endocrinal disruptors, tobacco smoke, food additives, radiation, noise, metals, and microwaves. Chapters dealing with risk and methods for reducing risks are also included. The book ends with an industrial perspective, which suggests how integration of information on the effects of chemicals into corporate policies and practices for protecting health can be achieved. The scope is thus broad although not all embracing. The first impression I got onto re reading the chapter dealing with topics with which I am familiar was one of awe. The detailed inclusion is extensive, facts fall like snowflakes, and hardly a line seems to lack either the data from a study or experiment. This does not make for easy or rapid reading but it does make for an outstanding source of reference. Readers should look at the editor's 70 page review of ozone that includes reference to more than 300 sources to see what a detailed review actually should be. Recent references are included throughout.

The first detailed chapter is on ambient particulate matter (this and some other chapters on classic air pollutants) is by the editor. The chapter is fairly short and presents a summary of most of what one needs to know. There is a trace of a bias towards the United States literature and the discussion on the setting of standards is focussed sharply on United States practice. The much discussed ultrafine hypothesis is treated lightly and the author has not dwelt on the mechanisms of free radical formation that are currently being discussed. Recent work on the effects of particles in animal models are discussed. This is followed by a longer account of asbestos and other fibres.

The evidence for effects on health reviewed look like a computer screen. Don't be put off: the layout is easy to follow and aids the learning process. The book is divided into 22 short chapters—each being subdivided into about five sections. Each section is only two to three pages long and each deals with a specific topic. Reading a subsection takes only 8-10 minutes and the text is so focused that one can hardly avoid learning. Even in the stickier passages the style is conducive to rapid uptake. Some subsections are very short—for instance, dendritic cells covered in a page or so, acute phase proteins treated similarly. All the important aspects of modern immunology are covered, including transplantation, vaccination, tumour immunology, and immunotechnology.

This is an outstanding book for revising or relearning immunology. Much has changed in recent years but this book will bring you rapidly up to date. At £14.95 this is essential immunology!

R L MAYNARD

Environmental toxicants: human exposures and their health effects
Edited by: J M HARRINGTON

Correspondence, Notices, Book reviews

Occup Environ Med: first published as 10.1136/oem.57.7.503 on 1 July 2000. Downloaded from http://oem.bmj.com/ on January 11, 2021 by guest. Protected by copyright. 503
in depth, sifted, and summarised judiciously. A great deal of detail is provided—enough to make some pages hard reading. The chapter ends with a useful recapitulation of the key findings. The editor has contributed further chapters—on ozone and sulphur dioxide; these follow the same pattern: exhaustive detail, careful weighing, and balanced conclusions.

In reading other chapters from this book I wondered whether the authors could keep up to Lippmann’s standard. Mauderly has dealt with diesel exhaust, and yes, he has maintained the standard: about 40 pages and on reaching the end the reader wonders whether he need read more on this vexed issue. The summary of what can be learnt from the epidemiological studies should be reprinted—widely. This chapter compares very favourably with recent monographs on diesel exhaust.

As well as dealing with chemicals, noise and radiation are reviewed. I read the chapter with diesel exhaust, and yes, he has maintained the standard: about 40 pages and on reaching the end the reader wonders whether he need read more on this vexed issue. The summary of what can be learnt from the epidemiological studies should be reprinted—widely. This chapter compares very favourably with recent monographs on diesel exhaust.

The book is in four sections: the first “general approach” is only a few pages long; the second “patient presentations with toxicological causes”; the third “antidotes” and the fourth “chemical and biological agents”. The fourth section covers about 300 compounds or agents. In reviewing this book I looked up topics I thought I knew but topics that I knew I didn’t know enough about. In both cases I was pleased. Take gulf war syndrome or methaemoglobinaemia, or multiple chemical sensitivity. On each a spread of two pages is provided—and you can, just, read the two pages in 5 minutes. The information provided is focused and clear—the reader is given clear information and in both cases I was pleased. Take gulf war syndrome or methaemoglobinaemia, or multiple chemical sensitivity. On each a spread of two pages is provided—and you can, just, read the two pages in 5 minutes. The information provided is focused and clear—the reader is given clear information and in both cases I was pleased. Take gulf war syndrome or methaemoglobinaemia, or multiple chemical sensitivity. On each a spread of two pages is provided—and you can, just, read the two pages in 5 minutes. The information provided is focused and clear—the reader is given clear information and in both cases I was pleased. Take gulf war syndrome or methaemoglobinaemia, or multiple chemical sensitivity. On each a spread of two pages is provided—and you can, just, read the two pages in 5 minutes. On each a spread of two pages is provided—and you can, just, read the two pages in 5 minutes. The information provided is focused and clear—the reader is given clear information and in both cases I was pleased.

Who, then, is this book for? Not for the beginner I think, but as a source of reference for the professional environmental toxicologist it is unequalled. Faults? A certain and understandable bias towards the United States perhaps but not much else that I can see. The book has been well proofed and is remarkably free from misprints. In conclusion, an outstanding book that every environmental toxicologist should have. Good value at £96.50.

R L MAYNARD

The publishers of this 7 volume book have kindly provided me with volume 1. I have learned something of substances beginning A-B! For each compound information is provided on physical properties, occupational exposure standards, ecotoxicity, environmental fate, mammalian and avian toxicology, genotoxicity, and legislation. A section entitled “other comments” is appended, as is a useful list of references. Some entries are short—and not all these topics are covered for each. Take for example, picked at random, allyl chloroformate. This compound is not very toxic (LC50 (mouse)=2000 mg/m3), is corrosive, is classified as a toxic substance for transport purposes, is a respiratory irritant but I have no idea whether anybody has looked to see whether it is a carcinogen. We are also not told the uses of this chemical. Perhaps it is rare: the 12th edition of the Merck index does not list it at all! I then looked up for methyl nitrite: not listed. I wondered whether drugs were included—yes, amylobarbitone is included. Benzo(a)pyrene is much better treated: pages of useful data are provided.

So: this is the first volume of a reference text that is designed more for libraries than for individual purchase. At £1295.00 a set it is not cheap but free access to a web database version is provided with each paper copy. Useful? Yes, although as usual with encyclopaedias the thing you wanted to know may not be there!

R L MAYNARD
