Increased morbidity from nasopharyngeal carcinoma and chronic pharyngitis or sinusitis among workers at a newspaper printing company

Y-H Liu, C-L Du, C-T Lin, C-C Chan, C-J Chen, J-D Wang

**Objectives:** To determine the association between printing works and nasopharyngeal carcinoma as well as other diseases.

**Methods:** Demographic data were obtained for those who had worked in a particular newspaper company since its establishment in 1950. Through access to the data bank of the hospital records of the Labor Insurance Bureau for 1985–94, all workers were identified who had been admitted to hospital during their employment in the newspaper company. Multiple logistic regressions were performed to estimate the adjusted morbidity odds ratio (OR) for various diseases among the printing workers with cardiovascular diseases as the reference diseases. Biopsy specimens from patients with nasopharyngeal carcinoma were all subjected to in situ hybridisation of Epstein-Barr virus (EBV), and colocalisation of EBV and secretor component protein.

**Results:** Of the 1,564 people who had worked in this company, 579 of them were admitted to hospital at least once. Five out of 1,444 printing workers admitted to hospital were diagnosed with nasopharyngeal carcinoma compared with none of the other 435 non-printing workers admitted to hospital. The morbidity OR for nasopharyngeal carcinoma in printing workers was 57.0 (95% confidence interval [95% CI] 2.8 to 1155.3). The morbidity OR for benign skin tumours was 28.0 (95% CI 2.7 to 293.1). Chronic pharyngitis or sinusitis also showed significant relations with printing works with a morbidity OR 29.4 (95% CI 1.7 to 514.7). Using all other diseases as the reference diseases for calculation of morbidity ORs still showed a similar trend. In situ hybridisation of EBV encoded small nuclear RNA-1 (EBER-1) showed tumour cells free of the EBV in each biopsy specimen. Colocalisation of EBER-1 and secretor component showed that some tumour cells contained both secretor component and EBV signal in each case.

**Conclusion:** Printing works are associated with an increased risk of nasopharyngeal carcinoma, benign skin tumours, chronic pharyngitis or sinusitis, chronic liver diseases, and mechanical injuries. Induction of the development of nasopharyngeal carcinoma is probably not related to EBV infection in these patients.

**SUBJECTS AND METHODS**

**Data collection**

Before 1995, the year the Taiwan government implemented a national health insurance system, the Labor Insurance Bureau in Taiwan had provided medical insurance for all labourers who worked in a company with more than five workers. Nearly all the workers in public and private sectors joined the Labor Insurance Bureau. As the Labor Insurance Bureau coverage provides a free choice of doctors and hospitals, full coverage of medical service fees, and partial compensation (about 70%-80% depending on industrial sectors) for wages, our workers would use it whenever they have a major disease that requires admission to hospital. There were around 500,000 reimbursement records of admissions to hospital in the Labor Insurance Bureau each year from a population of about 7 million workers. Through access to the database of the Labor Insurance Bureau we retrieved the reimbursement data of determinations between printing works and nasopharyngeal carcinoma as well as other diseases.

**Abbreviations:** OR, odds ratio; EBV, Epstein-Barr virus; EBER-1, EBV encoded small nuclear RNA-1; ICD-9, ninth revision of the international classification of diseases; EBVCA, viral capsid antigen associated with the EBV; HBV, hepatitis B virus

There are various organic solvents, filler materials, and inks used in the printing factory. A survey of materials and substances used in the printing industry in 1978 showed that 2000 products were used, in which 300 chemicals were identified. Among the chemicals, 26 are known or suspected carcinogens according to the classifications made by the International Agency for Research on Cancer. The printing occupations have been related to an increased mortality and morbidity from lung cancer, bladder cancer, renal pelvis cancer, and chronic pharyngitis or sinusitis among workers at a newspaper printing company. There has never been any report on the association between printing occupation and nasopharyngeal carcinoma.

Nasopharyngeal carcinoma is uncommon in most populations, but it occurs with a high frequency in Chinese people, especially in those from the southern provinces of China and Taiwan. It has been the fifth leading malignant neoplasm for men and the sixth for women in Taiwan since 1983. Environmental, genetic, and viral factors have been postulated as important determinants of nasopharyngeal carcinoma. However, the pathogenesis of nasopharyngeal carcinoma still awaits further clarification.

At one particular newspaper printing factory there were reported cases of nasopharyngeal carcinoma identified during 1986 to 1993. We were requested by the labour union and the newspaper company to perform an epidemiological study to determine the associations between printing works and nasopharyngeal carcinoma as well as other diseases.
admissions to hospital during 1985–94. The data items included national identification number, age, sex, occupation, hospital, total medical expense, medical record number, insurance number, date and duration of the stay in hospital, as well as the ninth revision of the international classification of diseases ICD-9 code of medical diagnosis.

We also obtained a complete list of workers who have worked in the company since its establishment in 1950. It contained information on demographic characteristics, history of working in a news printing factory, date and duration of employment, etc.

The reimbursement data and list of workers provided by the company were linked together to extract information of the workers who had been admitted to hospital during their employment in the company, regardless of the diagnosis. The relational query by example provided by the Microsoft database software Foxpro was applied for the extraction of information. For any worker who had been repeatedly admitted to hospital due to the same disease we kept only one record.

Through the procedure we obtained the list of workers affected with nasopharyngeal carcinoma and interviewed them or members of their family about their working and health history. As all workers with nasopharyngeal carcinoma were extracted from the reimbursement data, we are confident that the reimbursement data are comprehensive. With their consent, we reviewed their medical records from different hospitals and summarised the initial symptoms and signs, date of diagnosis, clinical course, treatment received, pathological findings, clinical staging of the disease, and serological titre of antibodies against Epstein-Barr virus.

### In situ hybridisation of EBER-1 and double localisation of EBER-1 and secretor component

Paraffin sections from four out of five patients with nasopharyngeal carcinoma were obtained from four different hospitals, including National Taiwan University Hospital, Kaoshuang Medical College Hospital, Macky Memorial Hospital and Veteran General Hospital (one of the paraffin blocks was missed in Tri-Service General Hospital). The paraffin sections after deparaffinisation were subjected to in situ hybridisation for localisation of EBV encoded small nuclear RNA-1 (EBER-1) with antisense riboprobe as described previously. Some sections were counter stained with methyl green; others were not. In each case, stain with haematoxylin and cosin was also performed. At the same time we also performed double localisation of EBER-1 and secretor component protein (an IgA receptor) by immunohistochemistry with an antibody against secretor component and in situ hybridisation according to our previously published method.

### Data analyses

Descriptive analysis of the demographic data and work history of all workers and the workers who had been admitted to hospital was performed. The morbidity odds ratios (ORs) of various diseases due to the exposure in a news printing factory was calculated as in a case-control study, with the case being various diseases that resulted in admission to hospital of the worker. There were two control groups in this study. The first control group was workers admitted to hospital for cardiovascular diseases. We lumped all workers who were admitted to hospital due to diseases other than the diseases of interest and cardiovascular diseases as another control group. Multiple logistic regression analysis was used to estimate morbidity OR adjusted for age, duration of employment, sex, and other possible risk factors. The statistical package SAS/STAT PC 6.08 was used for data analyses.

### RESULTS

There were 1564 workers identified as having worked in the factory since its establishment in 1950. Of these workers there were 1326 men and 238 women; 336 of them had worked in the printing factory; 1228 workers worked in non-printing sectors. The mean (SD) age of the workers was 41.1 (9.4) years and the mean (SD) duration of employment in the company was 13.3 (8.2) years. Workers of printing factories were younger with shorter duration of employment than non-printing workers. The difference was not significant (table 1). A significantly higher proportion of men worked in printing than non-printing departments.

Of the 1564 people who had worked in this company, the total admissions to hospital was 796 during the observation period. After discounting repeated admission to hospitals with the same diagnosis, there were 579 workers who were admitted to hospital at least once. We first chose cardiovascular diseases as the reference. Morbidity ORs for nasopharyngeal carcinoma, benign skin tumours, chronic pharyngitis or sinusitis, chronic liver disease or cirrhosis, and mechanical injuries were significantly related to printing works. Five out of 144 printing workers admitted to hospital were diagnosed with nasopharyngeal carcinoma compared with none of the other 435 non-printing workers admitted to hospital. Because one of the 2×2 cells was zero, we added 1/2 to calculate the crude morbidity OR of nasopharyngeal carcinoma, which was 57.0 (95% confidence interval (95% CI) 2.8 to 1155.3, Fisher's exact test, p<0.001).

When workers admitted to hospital due to diseases other than the disease of interest and cardiovascular disease as control group, all diseases of interest showed a significant trend except chronic liver disease or cirrhosis of the liver, as shown in table 2.

The mean (SD, range) duration of employment of the patients with nasopharyngeal carcinoma in this printing factory was 13.5 (7.2, 4.5–20.2) years. The mean age of these patients at the time of pathologic proof of nasopharyngeal carcinoma was 44.7 (14.5, 35.5–70.5) years, table 3.

The initial symptoms included bloody rhinorrhea, neck mass, nasal obstruction, hearing impairment, blurred vision, ptosis, and diplopia. Three out of five patients received the serological test for antibodies against EBV. Only one patient had a normal antibody titre of the viral capsid antigen associated with the EBV (EBVCA) in IgA class. The other two patients showed EBVCA IgA 1:20 and 1:160 respectively. Two patients died in 1993 and the other patients did not show any evidence of recurrence after radiotherapy and chemotherapy (table 3).

Four cases of nasopharyngeal carcinoma biopsy specimens showed a picture of undifferentiated nasopharyngeal carcinoma, and one of them seemed to have a lymphoepitheliomatous carcinoma. In situ hybridisation of EBER-1 in the four cases showed some tumour cells without EBV signal. The EBV signal was found in a few tumour cells in two of them (cases 1 and 4) and was seen in more tumour cells in the other two (cases 3 and 5); in these some infiltrating lymphocytes also showed an EBV signal.

When double localisation of EBV and secretor component protein was performed, some tumour cells showed neither EBV signal nor secretor component protein; a few tumour cells showed both EBV signal and secretor component immunostaining; other tumour cells either showed secretor component only or EBV signal with a very weak secretor component, a picture identical with our previously published data.17

**DISCUSSION**

The aetiology of nasopharyngeal carcinoma is probably multifactorial. Although we have found an increased morbidity OR of nasopharyngeal carcinoma in printing workers, it does not necessarily follow that nasopharyngeal carcinoma was caused by printing works. Evidence and arguments strongly suggest such a possibility. Firstly, eating salty fish20–22 and taking herbal drugs,23 were reported to be risk factors for nasopharyngeal carcinoma. But none of our patients were smokers, they usually smoked less than 1 pack/day because the company policy prohibited smoking at the workplace for fear of explosion and fire. As four out of five patients were below 41 years of age at the time of diagnosis, they were unlikely to have accumulated more than 30 pack-years. Thus, smoking alone seemed inadequate to explain the increased risk of nasopharyngeal carcinoma among printing workers. Thirdly, as the income levels, which were major determinants for smoking and dietary habits,24 seemed similar (800 US$/month for printers v 650 for non-printing workers). The likelihood of a major difference in these lifestyle habits may be low. Because both printing workers and non-printing workers had been working in an air conditioned system, the factor of merely poor ventilation cannot explain the difference of occurrence. Rather, workplace exposure must have contributed a significant portion, given that workers were under a closed air condition system to conserve energy. We conclude that all the suspected risk factors for nasopharyngeal carcinoma are not likely to be confounding factors in this study.

In the Chinese population, the incidence of nasopharyngeal carcinoma is unusually high. The annual incidence of nasopharyngeal carcinoma in Taiwan was 4.2/100 000.1 In these 1564 workers with a mean duration of 13.3 working years, the total working years were around 20 800. The expected number of cases of nasopharyngeal carcinoma in the whole newspaper company should be 0.8 during this period. We identified five cases of nasopharyngeal carcinoma and all were printing workers. If the observed five cases were divided by the expected 0.15 cases of nasopharyngeal carcinoma in printing workers, the morbidity ratio was 32. The result was

very consistent despite selection of two different control
groups, either cardiovascular disease or all diseases other than
diseases of interest, as shown in Table 2.

As infection with EBV has been proposed to be closely asso-
ciated with the development on nasopharyngeal carcinoma,14–27 and one of our patients has a high titre of IgA antibody against EBVCA (1:160), there is a possibility that nasopharyngeal carcinoma in this patient may have been induced by EBV infection. However, although a positive EBV signal was found in some tumour cells in each case, we found that all four specimens of nasopharyngeal carcinoma con-
tained tumour cells free from EBV. This finding indicates that
EBV infection is not the only causative factor for the develop-
ment of nasopharyngeal carcinoma in these four cases, as we
found previously.26–27 Furthermore, the presence of EBV and
secretor component positive cells in the sections indicates that
EBV may infect the secretor component positive nasopharyn-
geal carcinoma tumour cells, instead of secretor component
negative tumour cells, through the endocytosis of EBV-IgA-
secretor component complex as we previously described, and
possibly that EBV was not a causative factor in the induction
of nasopharyngeal carcinoma in these patients.

Cancers of the lung, urinary bladder, and liver were once
reported to be associated with printing works.1–7 It is not sur-
prising that such carcinogens might have a similar effect on
the nasopharynx, especially in ethnic Chinese, of whom the
structure of the nasopharynx is generally narrower and more
easily deposited with aerosols compared with the nasophar-
ynx of white people. Printing workers have been exposed to a
panoply of potentially toxic substances, including pigments,
inks, solvents, resins, driers, plasticisers and wetting agents,7
which might have a direct irritative effect and produce chronic
pharyngitis or sinusitis. Printing ink mixed with mineral oil
might contain procarcinogens—such as benzoyl-a-pyrenes.
Some printing pigments contain toxic heavy metals—such as
cadmium and lead. The environmental monitoring in the
factory identified the presence of toxic solvents—such as
tetrachloroethane, benzene, toluene, styrene, and n-hexane.
We conducted an exposure assessment of chemicals in the print-
ing workplace and detected trace concentration of formalde-
hyde (1.4–31.1 µg/m3), sulfuric acid (0.03–0.13 mg/m3),
and aerosol of mineral oils (0.02–0.13 mg/m3) after there had been
some improvement in cleaning and ventilation of the workplace.25 Although they were below the permissible
concentrations, long term effects might still be hazardous,
especially under a combined exposure to other potential
carcinogens and in a closed system of indoor air conditioning.
These toxic substances may coexist as aerosol and precipitate
in the nasopharyngeal mucosa, causing repeated or chronic
inflammation or even malignant change after a certain induc-
tion time.

More than 90% of nasopharyngeal carcinomas in Taiwan
are undifferentiated, non-keratinising carcinoma diagnosed at
a mean age around 45.25–28 It was unusual to see that printing
workers with undifferentiated, non-keratinising carcinoma
had a mean age of 39.1 (Table 3). One possible explanation was
early carcinogenesis due to exposure of toxic substances.
Among the workers with nasopharyngeal carcinoma, four had
worked in the printing factory for more than 13 years before
the date of diagnosis. One worker only spent 4.5 working years
in the factory before the onset of nasopharyngeal carcinoma.
However, this worker admitted that he had worked in another
printing factory for 10 years before taking the current job.
Thus the induction period of nasopharyngeal carcinoma
would be more than 10 years.

Cardiovascular diseases were used as the reference diseases
because cardiovascular diseases were not reported to be asso-
ciated with printing works. We even used diseases other than
the disease of interest as a second reference group. The result
did not differ much. Except for chronic liver disease or cirrho-
sis of the liver, all diseases in table 2 remain significantly asso-
ciated with printing works. The reason why OR decreased
might be due to the effect of including some diseases that may
also be related to printing. As we only had complete data from
one newspaper company, the case number was relatively small
and the estimated 95% CI of the morbidity OR was wide.

Both skin and the liver are vulnerable to toxic chemicals in
printing factories because they are either the defence organ
against toxic substance or the organ of detoxification. Primary
liver cancer, cirrhosis of the liver, and skin cancer were
reported to be increased in printing workers.2–7 Organic
solvents used in the printing factory might cause liver injury
and the long term exposure to these solvents might contribute
to the development of cirrhosis of the liver. In Taiwan, hepato-
tis B virus (HBV) caused most cases of cirrhosis of the liver
and primary liver cancer.25 As the prevalence of HBV carriers in
printing and non-printing workers was similar (14.1% and
13.0%, respectively), the increased risk of cirrhosis of the liver
was probably related to work. We thought that a longer dura-
tion of follow up or increased numbers in the study
populations in the future might show a clearer tendency.
Fur-
ther study should identify whether these diseases progress to
the development of nasopharyngeal carcinoma. Occupational
injury remained a problem of concern in printing factories
and most injuries were reported to occur during the process
of cleaning or repair of machines.

Results from this study of a cohort containing a group of
workers from a newspaper printing company support the
conclusion that printing works are associated with an
increased risk of nasopharyngeal carcinoma, chronic pharyn-
gitis or sinusitis, cirrhosis of the liver, and mechanical injuries.
Health surveillance, hazard control, and a programme of
injury prevention should be implemented in all newspaper
printing factories.

ACKNOWLEDGEMENTS
