explored by Spearman rank correlation coefficients ($r_s$). We further applied supervised and unsupervised classification to investigate protein patterns by type of lung tissue.

**Results** Occupational exposure was associated with an up-regulation of NOTCH1 (radon: $r_s = 0.18$, 95% CI 0.02–0.33; arsenic: $r_s = 0.23$, 95% CI 0.07–0.38). MUC1 classified lung cancer from cancer-free tissue (failure rate of 2.1%), and HIF1A and NXK2–1 discriminated the major subtypes of lung cancer with a failure rate of 8.4%.

**Conclusions** These results suggest that the radiation-sensitive protein NOTCH1 can be up-regulated in lung tissue from uranium miners by level of exposure to pulmonary carcinogens. The distinct phenotypes of the major subtypes of lung cancer could be discriminated with cancer-related proteins.

**SALIVARY CORTISOL AND DEPRESSION - IS THERE AN ASSOCIATION IN A RANDOM SAMPLE OF PUBLIC SECTOR EMPLOYEES?**

1A V Agergaard Vammen, 2Thomsen, 3Mikkelsen, 4Bonde, 5Hansen, 6Andersen, 7Butchersen, 8Gyndrup, 9Kolstad, 10Kærlev, 11Kærgaard, 12Rugules, 13Mors. 1Bispebjerg University Hospital, Copenhagen, Denmark; 2Department of Occupational and Environmental Medicine, Bispebjerg University Hospital, Copenhagen, Denmark; 3Department of Public Health, University of Copenhagen and National Research Centre, Copenhagen, Denmark; 4Danish Ramazzini Centre, Department of Occupational Medicine, Herning, Denmark; 5Centre for Psychiatric Research, Aarhus University Hospital, Risskov, Denmark; 6Center for National Clinical Databases South, Odense, Denmark; 7National Research Centre for the Working Environment, Copenhagen, Denmark

**Objectives** To examine the effects of going to work and other saliva sampling concentrations on the occurrence of cortisol in saliva.

**Methods** The study is a cross-sectional population study of 3536 working persons with data on cortisol concentrations in saliva samples, one in the morning and one in the evening, and information on saliva sampling circumstances recorded by questionnaire.

We studied the effects on cortisol from sampling on a work day compared to a day off; number of hours worked; smoking; leisure time physical activity; sleep problems the night before sampling and other sampling circumstances. These factors were included as covariates in ordinary least square regression analyses with the log of cortisol in saliva (nmol/l) as the dependent variable. We adjusted for effects of age, sex and saliva sampling times and time from awakening.

**Results** Saliva sampling times were the major determinants of cortisol concentrations in saliva, including linear and quadratic effects. Morning cortisol was 23% higher on work days than on non-work days ($p < 0.0001$), controlling for sampling and awakening times and other potential confounders. This effect was independent of age, indicating that the acute and rather strong HPA axis response to an anticipated stressor (going to work) was not attenuated by almost daily repeats during many years of work. Working seven hours increased the mean of morning and evening cortisol by 11% ($p < 0.0001$). Smoking, leisure time physical activity and use of painkillers also had significant effects.

**Conclusions** The anticipation of going to work seems to elicit a rather strong acute increase in morning cortisol. This response was not attenuated by increasing age as one would expect if frequently repeated HPA-axis activations eventually leads to a reduced HPA-axis response to acute stressors.

**EFFECTS ON CORTISOL IN SALIVA FROM GOING TO WORK AND OTHER SALIVA SAMPLING CIRCUMSTANCES. RESULTS FROM A LARGE EPIDEMIOLOGICAL STUDY**

1M Mikkelsen, 1Thomsen, 1Andersen, 1Bonde, 1Gyndrup, 1Kolstad, 1Kærlev, 1Kærgaard, 1Rugules, 1Vammen, 1Hansen, 1Bispebjerg University Hospital, Copenhagen, Denmark; 2Regional Hospital Herning, Herning, Denmark; 3Aarhus University Hospital, Århus, Denmark; 4Odense University Hospital, Odense, Denmark; 5National Research Centre for the Working Environment, Copenhagen, Denmark

**Objectives** Previous occupational studies suggest that 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) exposure may be associated
Abstracts

with non-Hodgkin lymphoma (NHL) but findings are inconclusive. Mechanistic studies using global biochemical profiling (metabolomics) could provide supporting evidence for such an association by identifying relevant biological pathways. We applied metabolomics to a cohort of TCDD exposed workers.

Methods 81 workers who had been exposed to either high (n = 43) or low (n = 38) TCDD levels more than 30 years before serum collection and 63 non-exposed workers (from a comparable factory but without TCDD exposure) were included in the study. Serum ion metabolites were detected using Ultra high Pressure Liquid Chromatography (UPLC) coupled online to a Q-TOF Premier mass spectrometer with a scan range of 70–1000 m/z. Current plasma levels of TCDD (TCDDCurrent) were determined by high-resolution gas chromatography/isotope dilution high resolution mass spectrometry. TCDD blood levels at the time of last exposure (TCDDmax) were estimated using a one-compartment first order kinetic model. Differentially expressed metabolites were identified using partial least squares (PLS) regression, and Bayesian stochastic search variable selection with spike-and-slab priors of (nonlinear) generalised additive models.

Results Features that were present in all QC samples and had a coefficient of variation CV <30% were included in the present analyses (n = 421 features). PLS and Bayesian stochastic search variable selection regression analyses revealed no obvious metabolic perturbations associated with TCDD serum levels.

Conclusions This is the first global metabolomic analysis related to TCDD exposure. No significant features were identified. It is concluded that TCDD exposure at levels present in this study does not lead to significant perturbations of the serum metabolites.

118 OCCUPATIONAL RISKS IN THE BUILDING AND PUBLIC WORKS SECTOR IN MOROCCO

H Hami, Z AAzouzi, D Raougui, A Soulaimani, A Mokhtari, O T Ahami, Kenitra, Morocco; Ibn Tofail University, Kenitra, Morocco

Objectives Occupational injuries represent a considerable part of the injury burden to society, affecting people in the most productive years of their lives. Building and public works sector is recognised by its high frequency of occupational injuries. Kenitra city is the most important city in the Gharb plain region (NW of Morocco) where different new constructions are installed. This study aims to describe the profile of occupational injuries occurring in the building and public works sector in Kenitra city.

Methods A descriptive retrospective analysis of occupational injuries notified in the delegation of employment of Kenitra in 2008–2009, was performed. The results do not include occupational diseases or journey accidents.

Results In 2008–2009, 305 workers were victims of an accident in the work, which 21 died. Victims are often men (91.8%). According to data recorded, the risks in building and public works sector are higher than in other sectors (working at height, working on moving equipment, handling important). Accidents in this sector are caused by machinery, falling materials and falls from height. These accidents caused a temporary and permanent disability (73.8% and 19.3% respectively).

Conclusions Occupational injuries could have serious consequences. Measures are needed to ensure safety and protect workers’ health.

119 RENAL EFFECTS INDUCED BY OCCUPATIONAL CO-EXPOSURE TO CADMIUM AND LEAD IN METALLURGY WORKERS

R H Habib, D Lison, C D’Hoese, J Weyler, E De Groot, A De Schryver, L V Lambert, M van Sprundel, University of Antwerp/Occupational Health Service Mensura, Wilrijk, Belgium; Louvain Centre of Toxicology and Applied Pharmacology, UCL, Brussels, Belgium; Laboratory of Pathophysiology, University of Antwerp, Antwerp, Belgium; Department of Epidemiology and Social Medicine, University of Antwerp, Antwerp, Belgium; Umicare PMR, Department of Health & Safety, Hoboken, Belgium

Objectives Research on the effect of co-exposure to Cd and Pb on the kidney is scarce. The objective of the present study was to assess the effect of co-exposure to these metals on early renal biomarkers.

Methods Cd in blood (Cd-B), Cd in urine (Cd-U), Pb in blood (Pb-B) and urinary renal biomarkers i.e., microalbumin (µ-Alb), beta-2-microglobulin (β-MG), retinol binding protein (RBP), N-acetyl-β-D-glucosaminidase (NAG), intestinal alkaline phosphatase (IAP) were measured in 122 metallurgic refinery workers examined in a cross-sectional survey. In order to explore the effect of Pb on the association between Cd and renal biomarkers (i.e., effect modification or interaction), we performed a multiple linear regression analysis (adjusting for age and pack-years of smoking) including an interaction term Pb x Cd.

Results The median Cd-B, Cd-U, Pb-B were: 0.8 µg/l (IQR = 0.5, 1.2), 0.5 µg/g creatinine (IQR = 0.3, 0.8) and 158.3 µg/l (IQR = 111.0, 219.3), respectively. The statistically significant interaction term Pb-B x Cd-B indicates that the impact of Cd-B on the enzymes NAG and IAP was only evident among workers with Pb-B concentrations ≥ 75th percentile. The association between Cd-U and the renal markers NAG and RBP was also evidenced when Pb-B ≥ 75th percentile. No statistically significant interaction terms were observed for the associations between Cd-B or Cd-U and the other renal markers under study (i.e., µ-Alb and β2-MG).

Conclusions Our findings indicate that Pb modifies (increases) the strength of the association between Cd and early renal biomarkers.

120 RENAL DYSFUNCTION AND POLYMORPHISMS IN METALLOTHIONEIN 2A IN A CHINESE POPULATION EXPOSED TO CADMIUM

C X Chang, J T Jin, Fudan University, Shanghai, China

Objectives Cadmium (Cd) toxicity of the kidney varies between individuals despite similar exposure levels. In humans Cd is mainly bound to metallothioneins (MT), which scavenge its toxic effects. Here we analysed whether polymorphisms in MT genes MT2A influence Cd-related kidney damage.

Methods In a cross-sectional study N = 566 volunteers were selected from three areas in South-Eastern China, which to varying degree were Cd-polluted from a smelter (control area [median Cd in blood B-Cd = 1.38 µg/l], moderately [B-Cd = 4 µg/l] and highly [B-Cd = 9.5 µg/l] polluted areas). (control area [median Cd in urine U-Cd = 2.01 µg/g Cr], moderately
