NIGHT WORK AND BREAST CANCER RISK AMONG MARGINAL STRUCTURAL MODELS IN OCCUPATIONAL EXPOSURE TO PM2.5 - A SHORT-TERM FOLLOW UP OF A LARGE SCALE POPULATION

Objectives To apply Marginal Structural Models (MSM) to address healthy workers survivor effect in a cohort study of active workers when time varying variables on health status and exposure are measured.

Method We used Cox MSMs and inverse probability weighting to assess the effect of PM_{2.5} exposure on incident ischaemic heart disease (IHD) in an active cohort of 11 966 US aluminium workers. The outcome was assessed using medical claims data from 1998 to 2012. Quantitative exposure metrics of current exposure to PM_{2.5} were dichotomized using different cutoffs and effects were assessed separately for smelters and fabrication. Risk score based on insurance claims was available as a time varying health status variable.

Results Defining binary PM_{2.5} exposure by the 10th percentile cut-off, health status was affected by past exposure and predicted subsequent exposure in smelters, but not in fabrication. A Traditional cox model was appropriate for fabricators; the hazard ratio was 1.51 (95% CI: 1.12 – 2.06) and was attenuated when considering higher exposure cutoffs. In smelters, Cox MSM Hazard Ratios for IHD comparing the effect of exposure in a population had everyone always been exposed to everyone always unexposed, using the 10th percentile exposure cutoff was 1.83 (95% CI: 1.14 – 2.94). Higher exposure cutoffs also resulted in attenuated effects.

Conclusions Marginal Structural Models can be used in active employment occupational cohorts to address time varying confounding. Results from the current study suggest that occupational exposure to PM_{2.5} in the aluminium industry increases the risk of IHD in both smelters and fabrication.

DIRECT EXPOSURE TO METALWORKING FLUID AEROSOLS AND CHRONIC OBSTRUCTIVE PULMONARY DISEASE IN A COHORT OF U.S. AUTOMOTIVE INDUSTRY WORKERS

Objectives Exposure to metalworking fluid (MWF) causes respiratory outcomes such as asthma and chronic bronchitis, as well as symptoms including phlegm and wheezing. Chronic obstructive pulmonary disease (COPD) encompasses these outcomes, and so is a potential result of MWF exposure. Recent evidence based on g-estimation suggests that reducing exposure to MWF would substantially decrease years of life lost due to COPD. The objective of this analysis is to examine the exposure-response relationship between direct exposure to MWF and COPD mortality in a large occupational cohort.

Method Hazard ratios were estimated using Cox proportional hazards models for the association between cumulative exposure to the thoracic fraction (PM_{10.8}) of straight, synthetic, or soluble MWF and COPD mortality. Subjects directly exposed to each fluid type were compared to those who were never directly exposed (assembly workers).

Results Hazard ratios for exposure quartiles increased in a non-monotonic fashion, with a maximum of 1.6 for straight, 1.4 for soluble, and 1.5 for synthetic, reflecting an increased risk of COPD for exposed subjects. However, none of the HRs were significant at the 95% confidence level. Indirect adjustment for
cigarette smoking (based on smoking rates in a cross-sectional survey) did not influence the estimates.

Conclusions While the results of this analysis did not reach statistical significance, they provide evidence supporting previous studies showing a risk of COPD associated with MWF exposure. The hazards presented are likely to be underestimates of the true association between COPD and MWF, due to the healthy worker effect.

0225 CANCER, MORTALITY AND ACUTE MYOCARDIAL INFARCTION IN WORKERS EXPOSED TO RESPIRABLE CRYSTALLINE SILICA DUST AT A SWEDISH PORCELAIN FACTORY

1,2Pernilla Wibert, 3Magnus Alderling, 3Magnus Svantengren, 1,2Per Gustavsson, 1Nils Plato. 1Karolinska Institutet, Stockholm, Sweden; 2Stockholm County Council, Stockholm, Sweden; 3Department of Medical Sciences, Uppsala, Sweden

10.1136/oemed-2014-102362.96

Objectives Exposure to silica dust is a health hazard in the ceramic industry. We studied cancer, mortality and acute myocardial infarction (AMI) among workers at a Swedish porcelain factory.

Method Annual average of exposure levels were estimated from 436 personal measurements of respirable crystalline silica dust (RCS) from 1971–2006. We investigated mortality, incidence of cancer, and first time event of AMI in men and women employed for at least one year at the factory in 1958–2009. We also studied the effect of latency, duration and cumulative exposure.

Results RCS-levels among highly exposed workers were five times higher than the OEL and ten times higher in the early 1970s as in 2000. We found a non-significant elevated risk for lung cancer, (SIR 1.39; 95% CI 0.79–2.25) and a significant elevated risk of squamous cell carcinoma in men (SIR 2.37; 1.02–4.66).

Mortality from respiratory diseases was increased (SMR 1.75; 1.22–2.44), especially in men (SMR 1.86; 1.22–2.70). Among women, the risk for mortality from diseases of the circulatory system and incidence of AMI was elevated but not statistically significant. We found no dose-response relationship. There were eight cases of silicosis, and seven appeared with more than 30 years latency.

Conclusions The increased risk for lung cancer and mortality from respiratory diseases was expected in view of the well-documented harmful effects of RCS. The tendency among women for increased mortality from diseases of the circulatory system and an increase in the incidence of AMI should be investigated in further studies.

0228 PERCEIVED WORKPLACE DISCRIMINATION AND SELF RATED HEALTH IN THE CHILEAN WORKFORCE

Junhee Cho, Devan Hawkins, Laura Kernan, Manuel Cifuentes. University of Massachusetts Lowell, Work Environment, Lowell, USA

10.1136/oemed-2014-102362.97

Objectives Increased research shows that perceived discrimination adversely affects physical and psychological health. Even though discrimination or concealed racism is an important characteristic of the Chilean society, which can be confirmed historically, it is not perceived as an important social problem for mainstream Chile. This paper aims to estimate the prevalence rate of workplace perceived discriminatory experience (WPDE) and its association with self-rated health status in the Chilean workforce.

Method Data from the first national survey on employment, work, and health in Chile. Study population of 9720 selected by multistage random sampling drawn to be representative of the entire working population. Study participants were asked about their WPDE (multiple questions) and general self rated health status (one question). Adjusting by demographic and socioeconomic factors, multivariable Poisson-log generalised linear mixed models were used to estimate the association between WPDE and self-rated health.

Results Approximately 17% reported being a victim of WPDE. Age, income, education, and minority (nine ethnicities) were strongly associated with WPDE. Female workers showed higher rate (19.6%) of WPDE than male workers (15.6%). After simultaneously controlling for potential confounders, WPDE was positively associated with poor self-rated health (PR = 2.12, CI = 1.46–3.05).

Conclusions There is positive association between WPDE and poor self-rated health in Chile. These results may be used to emphasise the importance of enacting preventive and protective workplace discrimination policies. Further research is required to study the causal mechanism of the link and best preventive and protective measures.

0231 ACUTE INFLAMMATORY RESPONSE TO SECONDHAND SMOKE EXPOSURE AMONG NON-SMOKING CONSTRUCTION WORKERS: A REPEATED MEASURES STUDY

1Jennifer Bruno Garza, 2Jinming Zhang, 3Shona Fang, 2Jason Wong, 2David Christiani, 1Jennifer Cavallari. 1University of Connecticut Health Center, Farmington, CT, USA; 2Harvard School of Public Health, Boston, MA, USA

10.1136/oemed-2014-102362.98

Objectives This study aimed to characterise the cardiovascuclar inflammatory response to secondhand smoke (SHS) exposure among non-smoking construction workers.

Method Non-smoking workers (n = 27) were recruited from a local union and monitored inside a union hall while exposed to SHS over approximately 6 h. Using a repeated measures study design, blood samples were taken before SHS exposure (baseline), immediately following SHS exposure (post) and the morning following SHS exposure (next morning). Inflammatory markers including acute phase proteins (SAA, CRP), adhesion molecules (s-ICAM, s-VCAM), and inflammatory cytokines (IL-1, IL-2, IL-6, IL-8, IL-10, TNF-alpha, VEGF) were analysed. Linear mixed effects regression models were used to examine within-person changes in inflammatory markers at post and next morning compared to baseline. Exposure-response relationships with TWA PM2.5 were also examined using mixed effects models. All models were adjusted for age, BMI and circadian variation.

Results There was a decrease in SAA (baseline = 2322 ng/ml, post = 1949 ng/ml, p = 0.04) and TNF-alpha (baseline = 9.6 pg/ml, post = 8.4 pg/ml, p < 0.01) post exposure, as compared to baseline. There was a decrease in IL-10 (baseline = 5.9 pg/ml, next morning = 6.5 pg/ml, p < 0.01) next morning compared to
