Dusts and Fibres

DOES LUNG CANCER INCIDENCE AND MORTALITY DIFFER WITH THE TYPE OF ASBESTOS FIBRE?: EVIDENCE FROM WESTERN AUSTRALIA

Nita Sodhi, 1,2 Nick deKlerk*, 1 Peter Franklin, 1,3 Fraser Brims, 4 Susan Peters, 1 Nola Olsen, 1,3 Bill Musk, 1 The University of Western Australia, Perth, WA, Australia; 2Telethon Kids Institute, Perth, WA, Australia; 3Sir Charles Gairdner Hospital, Perth, WA, Australia; 4Utrecht University, Utrecht, The Netherlands

Background Crocidolite is known to be the most carcinogenic form of asbestos for mesothelioma. This study aimed to assess if there was a difference between crocidolite and mixed asbestos fibre exposure for rates of lung cancer incidence and mortality after adjusting for smoking.

Methods Administrative datasets were used to identify lung cancer incidence and deaths in three Western Australian cohorts of people exposed to: crocidolite as miners and millers at Wittenoom; crocidolite as residents of Wittenoom; and mixed asbestos fibres occupationally. Multivariable Poisson regression models were used to compare the 5 year incidence and mortality rates between these cohorts after starting a health surveillance program. Explanatory variables included radiological evidence of asbestosis and cumulative asbestos exposures as determined through our Asbestos Job-Exposure Matrix (AsbJEM) after adjusting for smoking pack years, time since smoking cessation, age and sex.

Results The 5 year lung cancer incidence (n=176) and mortality (n=125) rates increased with radiological evidence of asbestosis (2.4-fold), increasing cumulative asbestos exposure and smoking pack years. Compared with crocidolite miners and millers, Wittenoom ex-residents had the lowest rates (Incidence Rate Ratio (RR): 0.31, 95% CI: 0.15–0.67; and Mortality RR: 0.39 95% CI: 0.17–0.88). However, there were no significant differences identified between people occupationally exposed to mixed asbestos fibres (Incidence Rate Ratio (RR): 0.92, 95% CI: 0.61–1.39; and Mortality RR: 1.07 95% CI: 0.66–1.73) and Wittenoom workers.

Conclusion Mixed asbestos fibre exposure seems to be an equally potent cause of lung cancer as crocidolite after adjusting for smoking history.

Occupational Medicine (SCOM/Modernet)

FINDINGS FROM THE FIRST YEAR OF MAREL: THE ITALIAN NETWORK ON WORK-RELATED DISEASES

Stefania Curti*, 1 Stefano Mattioli, 1 Pier Luigi Cocco, 1 Alfonso Cristaudo, 2 Marco dell’Omo, 1 Giovanni Mosconi, 1 Giuseppe Campo, 2 Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy; 3Department of Public Health, Clinical and Molecular Medicine, University of Cagliari, Cagliari, Italy; 4Unit of Occupational Medicine, University of Pisa, Pisa, Italy; 5Unit of Occupational and Environmental Medicine, Department of Medicine, University of Pergia, Pergia, Italy; 6Unit of Occupational Medicine, Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy; 7Department of Work and Environmental Medicine, Epidemiology and Hygiene, National Institute for Insurance against Accidents at Work (INAIL), Rome, Italy

Background Detecting new disease-exposure associations is an important public health issue. We created a pilot network (MAREL - MALattie e Rischi Emergenti sul Lavoro) of occupational disease consultation centres of Italian university hospitals to which patients are referred for potentially work-related diseases.

Methods The MAREL network currently includes five occupational disease consultation centres of university hospitals located in central-northern Italy. Patients are referred to these consultation centres by their general practitioners, occupational physicians or other specialists for the investigation of the putative occupational origin of the disease. Each centre collects cases of putative occupational origin through a structured consultations process and standardised data collection form. We collect data on: diagnosis; personal habits; occupational history; exposure assessment for potentially associated risk factors; physician’s opinion on the possible causal relationship between disease and occupation. Data are coded according to national and international classifications.

Results The data collection started in 2016. We collected 1516 cases of putative occupational diseases. Intervertebral lumbar disc degeneration was the most represented condition (n=170, 11.2%). Apart from musculoskeletal disorders, cases of asthma were the most frequently reported (n=59, 3.9%). About 11% of patients were construction workers. The most frequently reported exposures were: manual material handling (29.5%, out of 1811), hand-arm vibrations (13.9%), and repetitive movements of the upper limb (10.9%).

Discussion The MAREL network will be expanded to other occupational disease consultation centres in 2017 with the aim to contribute to already existing surveillance systems (i.e. MALPROF) by the detection of new and emerging occupational diseases and risks.

Department of Environmental and Occupational Health, National Cheng Kung University, Tainan, Taiwan

Ocular trauma in the workplace is a worldwide cause of visual morbidity, but is largely preventable. We established a pilot surveillance system of occupational eye injuries at emergency service of National Cheng Kung University Hospital (NCKUH) from Feb 2015 to Feb 2017. During the study period, 114 events of occupational eye injuries were collected with 22 patients further hospitalised. Among them, 3 cases of severe ocular trauma were accompanied with other injuries resulting in an Injury Severity Score of more than 16. Foreign body injury (28%, n=32) and chemical burn (21%, n=24) were the most frequent eye injuries. Notably, 12 cases (10.5%) eyeball rupture were identified. The total medical costs charged through the NCKUH were about 66,000 USD for these ocular trauma patients, counting emergency and hospitalisation fees within 90 days after the first encounter. Eyeball ruptures accounted for 57.5% of the total medical charges. Only about 18% of occupational ocular trauma cases were reported to the National Labour Insurance and would usually be compensated. This study highlights the urgent needs of comprehensive compulsory regulations of recognition and report, compensation, and prevention and control of occupational eye injuries in the workplace of Taiwan.

**PREDICTING THE IMPACT OF THE EU VIBRATION DIRECTIVE ON THE PREVALENCE OF VIBRATION WHITE FINGER (VWF), CARPAL TUNNEL SYNDROME (CTS) AND SENSORINEURAL SYMPTOMS ACROSS EUROPE**

Objectives EU directives can lend themselves to evaluation through natural experiments because of the freedom regarding their implementation within individual countries. Natural experiments may be criticised because of the lack of direct casual evidence for a relationship between the intervention and the exposure or disease outcome. Such experimental designs could be strengthened by an a priori estimate of the impact of an intervention. Here we aim to predict the impact of EU Directive 2002/44/EC on VWF, CTS and sensorineural symptoms (HAVS).

**Methods** Previously we described the development of a Markov chain Monte Carlo accelerated failure time model to predict the incidence and prevalence of HAVS. The model was developed using longitudinal data from Italian workers and validated using published data for Swedish and UK workers, and compensation data from the Czech Republic. For the next step we have used the exposure data from the Eurofound European Working Conditions Survey from 2000 to 2015 and population level demographic data to predict the impact of the directive on HAVS in Europe.

**Results** The model predicted that a reduction in vibration exposure to 5 m/s² (i.e. complete success of the directive) would result in a reduction in lifetime prevalence of VWF of around 23% in the UK. Predictions of the variation in impact according to differing reductions in exposure and across different age groups will be presented for the UK and other countries.

**Conclusion** Future work will compare these estimates of the impact of the directive using routinely collected data in European countries.

**ANALYSIS OF INFECTIOUS DISEASE PREVALENCE AMONG SEMICONDUCTOR MANUFACTURING WORKERS WITH NON-HODGKIN’S LYMPHOMA**

Jung-min Sung*, Sang-gil Lee, Eun-A Kim. KOSHA, Ulsan, Republic of Korea

**Introduction** The Occupational Safety and Health Research Institute (OSHRI) established a cohort of former and current workers in six semiconductor-manufacturing companies in South Korea, to determine the incidence of occupational cancer. This study compared the prevalence and incidence of general illnesses between patients with non-Hodgkin lymphoma (NHL) and a control group.

**Research Methods** After identifying 43 workers with NHL, OSHRI established a sex- and age-matched control group. The NHL cohort and control groups were compared for the prevalence of infectious diseases before and after diagnosis. The prevalence of infectious diseases was based on diagnostic data collected from National Health Insurance information. Disease names were determined by the ICD-10 disease code.

**Outcomes** Prior to the diagnosis of NHL, there was no significant difference in the prevalence of bacterial and viral diseases between the groups. However, following the diagnosis of NHL, the prevalence rates of viral and bacterial infections were significantly higher in the NHL group. Significant differences were found in the prevalence of herpes zoster, cytomegalovirus, and tuberculosis.

**Conclusion** Prior to the diagnosis of NHL, there were no significant underlying diseases in the NHL cohort group when compared to the control group. Therefore, we concluded there is no relationship between underlying infectious disease and NHL development. However, the probability of contracting opportunistic infections was higher in the NHL group.
