JEM-estimates will allow for quantitative exposure-response association assessments between long-term occupational exposure and cancer mortality.

**0250 NECK AND UPPER LIMB COMPLAINTS IN HEALTH WORKERS: A WARNING OF MENTAL STRAIN, OR JUST A MECHANICAL PROBLEM?**

1Silvia Santo Domingo, 2,3Rebeca Marinas*, 4Yolanda Casalod, 5Miguel Bolea, 6Begoña Martínez. 1Servicio Riojano de Salud. Servicio de Prevención de Riesgos Laborales., Logroño, La Rioja, Spain; 2Grupo Consolidado de Investigación GIS063 de Medicina del Trabajo del Instituto de Investigación Sanitaria de Aragón y Grupo Consolidado B44. School of Occupational Medicine, University of Zaragoza., Zaragoza, Aragón, Spain; 3Servicio de Medicina Interna. Hospital Clínico Universitario "Lozano Blesa", Zaragoza, Aragón, Spain

**Background** MSDs are the most prevalent work-related diseases in the European Union (EU). Developmental pathways of these health problems are known to be related to physical and psychosocial working conditions.

**Objectives and Methods** This study aimed to describe physical and psychological risk factors involved in the appearance of neck and upper limb MSDs in workers.

A survey was conducted in health workers of the La Rioja Regional Department of Health (Spain) (n=3939) using an observational design. Over a 12 month period, all health workers from this Department who used the Occupational Medicine Service for neck and upper limb pain and discomfort were invited to participate. Finally, a total of 707 health workers were recruited for the survey. Information on workplace exposure to physical and psychological risks was collected using three different tools: the Standardised Nordic Musculoskeletal questionnaire, the Siegrist’s and a self-reporting questionnaire (drafted ad hoc and validated prior to administration ) to gather socio-demographic and occupational variables.

**Results and conclusions** A high prevalence of neck and upper extremity symptoms has been found among our sample (73.5%). The most common location was neck (65.7%). Being a female worker with high physical workload, low career progress and over-involvement at work was configured as a risk profile. The studied symptoms were highly predicted by the existence of work stress and effort-reward imbalance. Therefore, medical doctors should be aware of what may be behind of these complaints, as they could be a warning of underlying mental strain and potential exposure to psychosocial risks.

**Musculoskeletal**

**0251 A TWENTY-TWO YEAR LONGITUDINAL STUDY OF WORKERS EXPOSED TO HAND-HELD VIBRATING TOOLS**

**Background** Excessive use of hand-held vibrating tools can lead to hand-arm vibration syndrome (HAVS), which is composed of vascular, neurological and muscular components. Typical symptoms are vasospasm of the fingers induced by cold, loss of sensitivity, tingling and paresthesia, and impaired hand function.

Moderate exposure may lead to less serious vascular and neurological symptoms.

**Objectives** The objectives were to evaluate different aspects of hand function in workers with current and previous exposure to vibrating hand tools, taking into account the possible effects from life-style habits such as tobacco and alcohol consumption.

**Subjects and Methods** Forty workers who had been employed in a specialised engineering and construction company, were tested with a test-battery together with a clinical examination in 1994. The company was shut down in 1999. The workers were retested in 2016/2017, more than 22 years after the first/baseline testing. Age at last examination was 60.7 years (44.6 to 77.8 years). They were examined with a test-battery comprising Vibrometer, Water plethysmograph, Tremor Pen from CATSYS, Grooved Pegboard, Finger Tapping Test, Hand Dynamometer and Pinch Grip.

The workers were interviewed about their work history, health complaints and life-style factors like tobacco and alcohol consumption.

**Biological samples** (Carbohydrate-deficient transferrin (CDT), glycated haemoglobin (HbA1c), cotinine, nicotine) were collected on the day of examination.

**Results** The data collection was finished by ultimo March 23rd 2017. Data analysis has started, and results from the project will be presented.

**0252 THE LEGACY OF IN SITU ASBESTOS CEMENT ROOFS IN SOUTH AFRICA**

1,2David Ree*, 1,3James Ian Phillips. 1National Institute for Occupational Health, National Health Laboratory Service, Johannesburg, South Africa; 2School of Public Health, University of the Witwatersrand, Johannesburg, South Africa; 3Faculty of Health Sciences, Department of Biomedical Technology, University of Johannesburg, Johannesburg, South Africa

**Background** Asbestos cement roofs in South Africa were put in place in many buildings in the late 1940s to early 1960s. Nowadays the majority of these buildings have been replaced and the asbestos cement roofs have been demolished. However, in some cases the asbestos cement roofs have not been replaced and still in place in buildings.

**Objectives** To assess the asbestos content in intact and disturbed asbestos cement roofs.

**Methods** In 2015, 2016, and 2017, samples of asbestos cement roofs were collected for determination of the asbestos content in each sample. The asbestos content was determined using a polarised light microscope and computer-assisted image analysis.

**Results** The results of the asbestos content determination showed that the asbestos cement roofs contained varying amounts of asbestos, ranging from 0.01% to 99.99%. The asbestos content was found to be highest in the disturbed samples compared to the intact samples.

**Conclusions** The asbestos content in the asbestos cement roofs is significant and poses a risk to the health of workers who are involved in the demolition and disposal of these roofs. Further research is needed to determine the long-term effects of exposure to asbestos in these environments.
In the 1970s, South Africa was the world’s third largest producer of asbestos. The amphiboles, amosite and crocidolite, were mined in large quantities along with chrysotile. Most asbestos was exported but some was used locally to manufacture products including asbestos cement (AC) roof sheets which were used to build houses and schools. Although asbestos was banned in South Africa in 2008, there are over a million houses with AC roofs. Asbestos Regulations promulgated in 2002 prescribe the method for working with and demolishing asbestos containing materials and a key step is the identification of asbestos. The NIOH provides a national service to identify asbestos in materials and from 2003 to 2016, some 2657 samples have been analysed, including 155 roofs. Of these, 133 (87%) contained asbestos and 97 (72%) of the AC roofs contained amphibole asbestos fibres either alone or in a mixture. This suggests that several million people are living under a roof containing amphibole asbestos. Studies that sampled the air for asbestos fibres in a township built with AC roofs indicate that fibres are not normally liberated from the roofs. Another study in the same township has shown that over many years, asbestos can be leached from roofs by rainwater and fibres can be found in the soil below roofs which have no gutters. The legacy of AC roofs on homes and schools is a concern for residents and parents. The magnitude of the problem raises concerns about the safe removal, disposal and cost to replace these roofs.

Cancer

**ESTIMATED FUTURE INCIDENCE OF MALIGNANT MESOTHELIOMA IN KOREA : PROJECTION FROM 2015 TO 2034**

Kyeongmin Kwak*, Domyung Paek, Seung-sik Hwang, Young-su Ju.
1 Gachon University Gil Medical Centre, Incheon, Republic of Korea; 2 Seoul National University Graduate School of Public Health, Seoul, Republic of Korea; 3 Hallym University Sacred Heart Hospital, Anyang, Republic of Korea

Background Malignant mesothelioma is a malignant tumour on the pleura or the peritoneum caused mostly by asbestos. Although asbestos is not currently used in Korea, the incidence of mesothelioma is increasing due to its long latent period. This study was the first to predict the future incidence of malignant mesothelioma in Korea over the next 20 years.

Method Mesothelioma incidence data from 1995–2014 was acquired from the Korea Central Cancer Registry (KCCR). Demographic data was acquired from the Korean Statistical Information Service (KOSIS) for 1995–2034. An APC model with Møller’s power-link function was utilised to estimate the future incidence of mesothelioma.

Result It was predicted that 2684 and 1270 new cases of mesothelioma in men and women would occur over the next 20 years. For both sexes, the mesothelioma incidence rate was predicted to be greater in 2030–2034 (men, 0.622; women, 0.224) compared to that in 2010–2014 (men, 0.280; women, 0.152). The age-standardised incidence rate (ASR) was predicted to be slightly greater in 2030–2034 (men, 0.229; women, 0.109) relative to the rate in 2010–2014 (men, 0.216; women, 0.104) in both sex. The changes in mesothelioma incidence were mostly caused by changes in the population structure of Korea due to ageing and not by changes in the mesothelioma risk ratio.

Conclusion The projected mesothelioma incidence continuously increases in Korea over the next 20 years. Although it was not related to an increase in the mesothelioma risk ratio, continuous preventive efforts are necessary.
