Methods Cross-sectional data from The Irish Longitudinal Study on Ageing (TILDA), a population-based study of 8175 people aged ≥50 years was analysed. Those in employment were grouped according to the occupational social classification, an internationally recognised categorisation widely used to analyse social and health variations. Statistical analyses were performed using SPSS (V22.0, SPSS Inc, IL). Tests for main effects were conducted using an ordinal logistic regression using a generalised linear model. The relationship between self-rated health and social class was examined with age, gender, educational status, medical history and multiple lifestyle factors (body mass index (BMI), smoking, alcohol consumption, physical activity) as the independent variables.

Results 30% (2440/8175) of the TILDA cohort were in employment at the time of the study and therefore included in the analysis. There was a statistically significant association between self-rated health and occupational social class after adjusting for independent variables as described above (p-value 0.014).

Conclusion There is a strong cross-sectional association between self-rated health and occupational social class in those at work over 50 years of age in Ireland. This association is preserved after adjusting for gender, age, past medical history, lifestyle behaviours and educational status. Further research is required to establish if this association persists among retirees. This study confirms the need to tailor health promotion and well-being programs to the different occupational social groups to maximise potential health benefits and to preserve employment among older workers.

1328 ATTITUDES TOWARD WORKING CONDITIONS: ARE EUROPEAN UNION WORKERS SATISFIED WITH THEIR WORKING HOURS AND WORK-LIFE BALANCE?
1Nuria Matilla-Santander*, 1Cristina Lidón-Moyano, 1Adrián González-Martín, 1Kailey Bunch, 2Juan Carlos Martín-Sánchez, 1Jose M Martinez-Sánchez. 1Group of Evaluation of Health Determinants and Health Policies, Sant Cugat del Vallès, Spain; 2Tobacco Control Unit, Hospital de Llobregat, Spain

Introduction Neoliberal economic globalisation has changed the definition of standard employment and this could be affecting work-life balance. The objective of this study is to describe the satisfaction with working hours and satisfaction with work-life balance and their association in the European Union (EU-28).

Methods This is a cross-sectional study based on data from the Flash Eurobarometer 398 among workers of the EU-28 from 2014 (n=13,683). We calculated percentages and their 95% confidence intervals (95% CI). We also fit a multi-level model with time (2014 as reference) as time-independent variables. Including time2 allows for the intercept and time-varying variables. Results Satisfaction with working hours and work-life balance was 80.62% and 74.48%, respectively, and was significantly higher among women. The highest percentages of satisfaction were found in Nordic welfare regime countries (90.2% and 85.3%, respectively). There was a statistically significant association between satisfaction with working hours and work-life balance (aPR=2.63, 95% CI: 2.28 to 3.04), and the magnitude of the association differed by individual and employment characteristics and welfare regime country classification. The main reasons declared for dissatisfaction were ‘excessive working hours’ (48.7%), ‘shift work’ (27.9%), and ‘inability to influence the work schedule’ (28.3%). Differences were observed according to sex and type of welfare regime.

Conclusion European Union workers are highly satisfied with their working hours and work-life balance, and there is a strong association between satisfaction with work-life balance and working hours. There are still differences between sexes and welfare regimes. The Nordic model of social policies should be considered to improve satisfaction with work-life balance in the rest of the EU-28.

247 THE EFFECTS OF OCCUPATION ON THE EVOLUTION OF BMI IN A BELGIAN EMPLOYEE POPULATION
1Martijn Schouteden*, 1Matthias Coene, 1Chris Verbeek, 1Marc Beurms, 1Lode Goddeeris. 1Idewe, External Service for Prevention and Protection at Work, Belgium; 1Katholieke Universiteit Leuven, Centre for Environment and Health, Belgium

Introduction During medical investigation, occupational health physicians collect huge amounts of scattered data about their patients. Recently, these data have been integrated into a single data warehouse. In the current study, this data warehouse has been addressed to study the evolution of BMI, and investigate how this trend is affected by the occupation of the employee, controlled for gender and age.

Methods Around 78 000 employees were followed-up from 1993 onwards, with following variables: BMI, age, sex, and iso encoded occupation. Multilevel analyses were performed to study the evolution of BMI, with time and time2 as time-varying variable, and sex, age at start of measurement and occupation as time-independent variables. Including time2 allows for modelling curvilinear trends over time. Random effects were allowed for the intercept and time-varying variables.

Results Over the 23 years of follow-up, we observed a high drop-out of around 90%. Nonetheless, all occupations were still represented at the last measurement. 52.8% was male, mean age was 34.34 years (SD=9.43) at the start of the study. Analyses showed that BMI increases curvilinear with age: the younger, the steeper the curve; Males have higher BMI than females. Occupation also has an effect: Highest BMI was observed with Service personnel of machinery and installations assemblers; the increase of BMI was highest for Leading functions. Random effects showed large inter-individual differences in BMI at starting point and on effect of time.

Discussion We’ve illustrated how the data warehouse can be accessed to answer substantive research questions. Differences in evolution of BMI seems to be related to occupation. The strong curvilinear effect probably indicates healthy worker effect. The high dropout might be explained by employees changing companies, companies changing external service, and/or the reach of retirement age.

253 THE ASSOCIATION OF AGE AND CHRONOTYPE IN DAY AND ROTATING SHIFT WORKERS OF A LARGE GERMAN CHEMICAL COMPANY
M Schuster*, M Claus, S Webendorfer, C Oberlinner. Corporate Health Management, BASF SE, Ludwigshafen, Germany

Introduction As shift work is necessary in large chemical companies, it is important to understand the effects that different chronotypes have on the work performance of day and rotating shift workers. The aim of this study was to investigate the association of age and chronotype in day and rotating shift workers of a large German chemical company.

Methods The study population consists of 1200 day and rotating shift workers of a large German chemical company. The workers were assessed using a validated questionnaire regarding their age, gender, and chronotype. The data were analyzed using univariate and multivariate regression analysis.

Results The results showed a significant association between age and chronotype in day and rotating shift workers. The older workers were more likely to be evening types compared to morning types, while the younger workers were more likely to be morning types compared to evening types. The association was strongest for rotating shift workers, with a stronger effect for older workers.

Conclusion The results indicate that age and chronotype are important factors to consider in the management of shift workers. The findings suggest that younger workers are more likely to be morning types, while older workers are more likely to be evening types. This may have implications for the scheduling of shift work and the design of training programs for shift workers.
