Results At the age of one there were no statistically significant differences among the adjusted mean language acquisition ITC-scores of the children in different exposure categories. The adjusted scores among boys were 30.1 (95% CI: 28.3 to 31.8) for no exposure, 29.7 (27.4–32.0) for low noise, and 29.3 (26.7–31.9) for moderate/high exposure. Among girls these were 33.7 (31.9–35.5), 33.8 (31.3–36.4), and 33.6 (31.3–36.0), respectively. No associations were found in analyses of social communication, speech production and language comprehension. Noise exposure was associated with lower scores among kindergarten teachers. At the age of two mean MCDI-scores did not differ significantly between the noise exposure groups. The adjusted mean scores for expressive vocabulary among girls were 295 (95% CI: 254 to 336) for no exposure, 303 (243–362) for low exposure, and 269 (212–326) for moderate/high exposure. Among boys the scores were 200 (154–246), 178 (111–246), and 225 (153–298), respectively.

Discussion We found no clear association between noise exposure during pregnancy and language acquisition among one- or two-year-old children.

Introduction The question about mediation between work and pregnancy is a real problem in industrialised countries, but in a country like ours, the issue is far away from being taken as a priority. Thus, we’ve chosen to conduct this prospective study about premature birth and working conditions trying to find a correlation between the two, while removing medical and obstetrical risk factors.

Methods The study was conducted in between January and December 2014. We’ve included women who had a job 6 months or more before the conception. To evaluate working conditions we’ve used the fatigue score developed by Mamelle. To evaluate the impact of working conditions on premature birth, we’ve monitored cervical length changes.

Results At first, we’ve gathered a selection of 68 pregnant women debating their follow up between 11 and 13 weeks of amenorrhea plus 5 days. An acceleration of the modification of the uterine cervix was noted within the group of women having a «Mamelle» score of 3.

Discussion The first epidemiological study bringing up the part of tiring working conditions in premature birth was conducted by Mamelle in France. After that, more authors, such as Mac Donald, got interested by the subject and implicated long working hours, rotating shifts and carrying heavy loads in the occurrence of premature birth. We took 18 mm as a limiting value for the length of the cervix under which intervention measures should be taken.

Conclusion Risk assessment of working conditions is the only deciding factor when it comes to the pursuit of work while being pregnant. The decision needs to be taken by both the attending and occupational physicians.
