Introduction ‘Workaholism’, an addiction to work, is a pathology which has been recognised since the 1970s. It is generally found in around 10% of workers, yet one study on doctors working in a hospital environment demonstrated that 30% suffered from the condition. This study’s objective is to evaluate the prevalence of workaholism among doctors in a university teaching hospital, and to analyse the links to working conditions and the imbalance between effort and reward.

Methodology Cross-sectional survey of doctors in a university teaching hospital, using an anonymous online questionnaire via Sphinx Online© software. The questionnaire consisted of general questions, specific questions on psychoactive substances (tobacco, alcohol, cannabis and others), Siegrist’s effort-reward imbalance questionnaire and the Work Addiction Risk Tests (WART) questionnaire. Results were analysed using Excel© and Biostat v.©.

Results There were 162 participants, a rate of 30% of relevant personnel. The principal psychoactive substance used by participants was alcohol: 81.3% of subject reported consuming it. An effort-reward imbalance was present in 18% of subjects who participated in the study. The risk of workaholic was identified in 48% of the cohort: 17% were high risk and 31% medium risk. There was a link between workaholism and effort-reward imbalance (p<0.001).

Conclusion The frequency of workaholism among doctors is much higher than the general population. From this study the link with work-related stress may help direct primary prevention efforts for this condition.

Introduction Burnout is common among healthcare workers with significant implications for caregivers and their patients. This study aims to establish the incidence of burnout among midwives and to investigate the extent to which exposure to traumatic perinatal events in work contribute to this.

Methods A cross-sectional study was carried out in a tertiary maternity hospital between March and May 2014. Anonymous voluntary questionnaires were circulated to all 248 clinical midwives and to investigate the extent to which exposure to traumatic perinatal events in work contribute to this. Demographic details, frequency and types of traumatic perinatal events encountered were recorded. The extent of distress experienced was documented on two visual analogue read in combinations to reflect the impact of the event and the resulting distress. Burnout was assessed using the Copenhagen Burnout Inventory which assesses the extent of burnout on three domains; personal, work-related and patient-related. Each domain is scored on a scale of 0–100, with a score of ≥50 considered to be indicative of significant burnout.

Results The response rate achieved was 55% (n=137). The mean scores for personal, work-related and patient-related burnout were 56.0, 55.9 and 34.3 respectively. Over 90% of respondents experienced a traumatic event in work in the previous year, with 58% reporting a frequency of monthly or greater for such events. The extent of distress reported by midwives was positively related to burnout (R²=0.16, p<0.01). A modest negative linear relationship exists between personal and work-related burnout scores and increasing age (p=0.25 and -0.27, p<0.01). Midwives with less midwifery experience (<10 years of experience) reported higher levels of burnout. Midwives with a higher number of children were also more likely to experience burnout.

Discussion This study shows that qualitative job insecurity is an important determinant of employee alcohol and drug use. Furthermore, learning opportunities (negatively related) and task autonomy (positively related) may relate to alcohol consumption. Our findings will be discussed in light of their theoretical and practical contributions.

1028 ASSOCIATION BETWEEN EMOTIONAL SYMPTOMS AND JOB DEMANDS IN THE ELECTRONICS FACTORY

1,2PC Chu*, 1,2YL Guo, 1,2PC Chen, 3UV Liu, 4CY Chen. 1Department of Environmental and Occupational Medicine, National Taiwan University and National Taiwan University Hospital, Taipei, Taiwan; 2Department of Environmental and Occupational Medicine, National Taiwan University Hospital Hsin-Chu Branch, Hsinchu, Taiwan; 3Institute of Occupational Medicine and Industrial Hygiene, College of Public Health, National Taiwan University, Taipei, Taiwan; 4National Institute of Environmental Health Sciences, National Health Research Institutes, Zhunan, Taiwan; 5Institute of Labour, Occupational Safety and Health, Ministry of Labour, New Taipei City, Taiwan

Introduction Emotional symptoms are related to work-related factors. The understanding of the association between emotional symptoms and job demands in the electronics industry is limited. The objective was to examine the relationships between emotional symptoms and job demands.

Methods We conducted a cross-sectional study, which enrolled 458 workers in the electronics factory. Personal factors, work-related factors, and emotional symptoms were assessed by the self-administered questionnaire. Emotional symptoms were comprised of depressive and hostility. The job demands included the following items: working under high pressure, working hours, workload, imbalance between job demands and workers’ abilities, monotonous job, physical risks, unclear understanding about job duties, conflicting demands, and socially isolation at work. Multiple logistic regression analysis was applied to explore the association between work-related factors and emotional symptoms.

Results Among the study population, 154 (33.6%) had emotional symptoms. In the simple logistic regression analysis, regular exercise (OR=0.46), working under high pressure (OR=3.05), working long hours (OR=2.42), high workload (OR=2.31), imbalance between physical and mental job (OR=1.73), conflicting demands (OR=3.94), and social isolation at work (OR=4.89) were significantly related to the presence of any symptom of depression or hostility. Further, in the multiple logistic regression model adjusted for other variables, regular exercise (OR=0.51, 95% CI: 0.30 to 0.88), working under high pressure (OR=1.84, 95% CI: 1.05 to 3.21), conflicting demands (OR=2.15, 95% CI: 1.30 to 3.57), and social isolation at work (OR=2.9, 95% CI: 1.23 to 7.30) were significantly related to the presence of any symptom of depression or hostility.

Conclusions Working under high pressure, conflicting demands, and social isolation at work may be the risk factors for emotional symptoms. Therefore, workplace mental health promotion should focus on not only education of lifestyle modifications (i.e. exercise), but also job demands.

656 MENTAL HEALTH AND QUALITY OF LIFE ARE STRONGLY ASSOCIATED TO OCCUPATIONAL STRESS: A STUDY WITH WORKERS FROM A YOUTH CUSTODY CENTRE IN BRAZIL

1Fernando Feijo, 2Cristiane Bunchen, 3Inaiara Kersting, 4Paulo Antonio Oliveira. 1Federal University Of Pelotas, Pelotas, Rio Grande do Sul, Brazil; 2Federal University of Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil; 3Federal University of Health Sciences, Porto Alegre, Rio Grande do Sul, Brazil

Introduction Workers from Youth Custody Centres are submitted to several occupational stressors in Brazil. Therefore, we aimed to investigate the impact of occupational stress in mental health and quality of life of workers from a youth custody centre.

Methods Cross-sectional study with a sample of 208 civil servants from a youth custody centre in southern Brazil. We used the Job Stress Scale (JSS) to analyse the exposure to psychological demands, job control and social support at work, based on the job strain model. Outcomes were measured using the Beck Anxiety Inventory (BAI), the Beck Depression Inventory II (BDI-II) and the World Health Organisation Quality of Life instrument – brief version (WHOQOL-bref) to evaluate anxiety, depression and quality of life of workers.

Results Physical, social relationships and environmental domains of quality of life had low mean scores in our sample. Job strain was associated with lower scores in all quality of life domains. Psychological demands and low social support were strongly associated to worse scores in quality of life. Anxiety and depression were also strongly associated to worse quality of life.

Discussion Occupational stress and bad mental health are associated to worse scores in quality of life in these workers.

621 KAROSHI SYNDROME AND VIOLENCE: EXTREME LABOUR STRESS ASSOCIATED TO DEATH BY ACUTE CARDIOVASCULAR EVENT: A CASE REPORT

P Garza*, A Ureña. Mexican Social Security Institute, Acapulco, Mexico

Introduction Karoshi, is the result of extreme work related stress by an excess of work, presenting acute cardiovascular episodes such as the cerebrovascular disease.

Methods A case report.

Results Male 46 years old, no important family history. Smoking and alcoholism denied, diagnosed with hypertension 5 years ago, keep it stable. He is a company manager. On 07/30/2009, when he was in his work area, he received an extortion call because he was the company’s manager, he later reported to the corresponding authorities, without having any preventive action or response against it. Afterwards, because of the social and economic situation of the state, the company felt obligated to reduce the amount of workers in a very impactful manner, by which the employee starts to supply the needs of other areas in addition to his own, registering more than 20 extra activities, added to the increase of his workday hours. In 2011, he presented affective flattening, irritability, insomnia, headaches, chest pain, lower back pain, and anxiety,
