illness play an important role in the context. Leaders serve as role models and therefore tend to have a huge impact on the pressure perceived by employees. Moreover, support from management, leadership qualities as well as leadership style tend to be an issue. Correlations often were no longer significant when other variables such as health problems, demographic variables or organisational factors were incorporated.

Discussion Results from quantitative and qualitative studies suggest that there is a correlation between leadership and presenteeism. However, results are not conclusive. Moreover, significant correlations disappeared when multivariate analyses were undertaken. Thus, results have to be interpreted with care.

446 NIGHT WORK AND COMMON MENTAL DISORDERS: ANALYSING OBSERVATIONAL DATA AS A NON-RANDOMISED PSEUDO TRIAL

1MS Beltagy*, 1JP Enttii, 2VA Valttia, 1-4MK Kivimäki. 1Department of Public Health, University of Helsinki, Helsinki, Finland; 2Department of Public Health, University of Turku, Turku, Finland; 3Department of Epidemiology and Public Health, University College London, London, UK; 4Finnish Institute of Occupational Health, Helsinki, Finland

Introduction This paper investigates the relationship between working regularly in night shifts for long periods and common mental disorders, including depression, anxiety disorders, severe stress, adjustment disorders, neurotic disorders and insomnia. The investigation of this association can help position intervention policies concerned with regulations of work schedule and workers’ mental health.

Methods A non-randomised pseudo trial was conducted on two populations of social and healthcare employees (the Finnish Public Sector Study) for a duration of eight years. Study one tested the effect of moving from continuous day work to night work in night shifts on the development of common mental disorders for 30 019 employees and study two examined the prevalence of several adverse psychosocial work factors among 446 employees who continued to work night shifts (odds ratio 1.99, 95% CI: 0.82 to 1.30) whereas workers; (odds ratio 1.03, 95% CI: 0.82 to 1.30) whereas both results were adjusted for several covariates.

Discussion Our paper introduces a novel approach to analyse observational repeat data on night work which is closer to randomised controlled trials than conventional epidemiologic analyses. The results from study one could not support a causal association between night work and the development of common mental disorders. However, study two shows increased recovery rates from common mental disorders when night workers change their work schedule back to day work. These findings suggest that change in work schedule may have a role in the prognosis of common mental disorders.

880 HEALTHY ENTERPRISE STANDARD (HES) EVALUATION: IMPACT ON ADVERSE PSYCHOSOCIAL WORK FACTORS AND PSYCHOLOGICAL DISTRESS

1-2M-C Letellier*, 1C Duchaine, 3M Vézina, 1K Aubé, 1-4M-M Mantha-Bélisle, 4H Sultan-Traib, 5ST St-Hilaire, 1C Brisson. 1Faculty of Medicine, Laval University, Quebec City, Canada; 2China-Quebec Research Centre, Population Health and Optimal Health Practices Unit, Quebec City, Canada; 3Institut national de santé publique du Québec, Quebec City, Canada; 4University of Quebec à Montréal, Montreal, Canada; 4Management School, University of Sherbrooke, Sherbrooke, Canada

Introduction Adverse psychosocial work factors are recognised as a significant source of psychological distress. The Healthy Enterprise Standard (HES) targets four intervention areas: Lifestyle, Work-life balance, Workplace environment and Management practices; this latter area referring to interventions aimed at improving the psychosocial work environment. The aim of this study was to evaluate the impact of implementing the HES on exposure to adverse psychosocial work factors and the prevalence of psychological distress among ten Quebec organisations.

Methods This was an intervention study with a before-after design derived from secondary data. Organisations adopted the standard of their own initiative and were responsible for implementing interventions. All active employees were solicited to participate before (T1=2849) and 24–38 months (T2=2560) following the standard’s implementation. At both time points, participants completed a questionnaire. Psychosocial work factors were assessed with the validated demand-control-support and effort-reward imbalance models. Psychological distress was assessed with the validated K6. Intervention exposure was measured by questionnaire and complemented by qualitative analyses.

Result The prevalence of low social support at work and high psychological distress decreased among all participants between T1 and T2. In organisations that were less exposed to interventions in the Management practices area, an increase in the prevalence of several adverse psychosocial work factors was observed whereas a decrease in the prevalence of these adverse factors was observed in organisations more exposed to Management practices interventions. Moreover, a more important decrease in high psychological distress was observed in organisations more exposed compared to those less exposed to interventions in this area.

Discussion These results suggest that organisational psychosocial interventions implemented in the context of this standard may be effective in reducing both adverse psychosocial work factors as well as high psychological distress and may therefore be an effective means to improve the mental health of workers.

93 THE INFLUENCE OF WORKPLACE SOCIAL CAPITAL ON HBA1C LEVELS AMONG JAPANESE WORKERS: A 2-YEAR PROSPECTIVE COHORT STUDY (J-HOPE)
