**Introduction** Workplace social capital (WSC) is hypothesised to be beneficial for employee health. We sought to examine the association between changes in WSC in relation to changes in HbA1c levels.

**Methods** Analyses included 2778 men and 684 women aged 65 and under working at six companies in Japan from the J- HOPE Study. The first survey was conducted between October 2010 and December 2011, and two follow-up surveys were conducted at approximately annual intervals. Questionnaires inquiring about workplace social capital and other characteristics were administered at each survey. Blood samples were obtained from participants at baseline and at the following two surveys. Linear regression analysis was performed to assess the cross-sectional and longitudinal association between WSC and HbA1c levels using Generalised Estimating Equations.

**Result** For women, higher level of WSC was cross-sectionally associated with lower HbA1c (standardised regression coefficient β = –0.020, 95% CI: –0.033 to –0.007). Longitudinally, similar associations were observed (β = –0.016, 95% CI: –0.030 to –0.003). No association was found among men. All explanatory variables were standardised before inclusion in each analysis.

**Discussion** WSC may have beneficial effects on glycometabolism in working women. The gender difference in associations may be partially explained by the socio-cultural context. Our findings lend weight to the notion that the pattern of association between WSC and HbA1c is both culturally contingent and gender-specific.

**Introduction** Workplace bullying has been described as an important determinant for many health outcomes, such as depression, suicidal ideation and sleeping problems. However its role as a possible determinant of musculoskeletal disorders is still on discussion. We aimed to evaluate the independent association between workplace bullying and neck/upper limb musculoskeletal pain in a sample of Brazilian civil servants.

**Methods** Cross-sectional study with a sample of 1616 workers from the Brazilian Federal Judiciary. The Negative Acts Questionnaire (NAQ-r) was used to measure bullying at work and an adapted version of the Nordic Musculoskeletal Questionnaire (NMQ) was used to evaluate neck and upper limb musculoskeletal pain. Poisson and logistic regressions were used to test and estimate associations of interest, controlling for confounders.

**Results** The overall prevalence of frequent (weekly or daily) neck and upper limb musculoskeletal pain was 49.9%. The prevalence of workplace bullying was 17.0%. In the regression analysis controlling for social, demographic and occupational confounders, workers exposed to bullying (weekly or daily negative acts) presented a 2.04-fold higher prevalence of neck and upper limb musculoskeletal pain than those who did not suffer bullying (p<0.001).

**Discussion** Our findings suggest that workplace bullying can be an independent risk factor for musculoskeletal pain in workers. New longitudinal studies are needed in order elucidate the role of workplace bullying in determining occupational musculoskeletal disorders.
company. In order to determine the prevalence of stress in a port company in Abidjan we conducted this study.

Method A cross-sectional descriptive and analytical survey was conducted from April 2015 to July 2016. In collaboration with the company’s managers, we sensitised staff on the concept of stress at work. The data were collected using three self-questionnaires (the 26-item KARASEK job content questionnaire, 12 items GOLDBERG self-assessment questionnaire for psychopathology, and the French version of the SIEGRIST questionnaire at 46 items).

Results The prevalence of stress was 54.6%. Stress came mainly from supervisors (63.7%) and was favoured by work situations such as emergency tasks (21.4%), poor organisation of work (20.4%), and Heavy workload (17.8%). More than two-thirds of stressed workers (64%) had psychological distress. Age $p=0.139$, gender $p=0.57$, workplace $p=0.65$, professional seniority $p=0.63$ and the hourly organisation of work $p=0.39$ had no statistically significant impact on the occurrence of stress.

Conclusion Stress is a major psychological risk requiring preventive measures such as listening cells and improved working conditions in human, technical and organisational terms.

1050 ASSOCIATION BETWEEN WORKPLACE SOCIAL CAPITAL AND JOB PERFORMANCE: A MULTILEVEL STUDY IN CHINA

Jing Wang, Jie Qi, Hongtao Huang, School of Public Health, Fudan University, Shanghai, China; Shanghai Pudong New Area Centre for Disease Control and Prevention, Shanghai, China

Introduction Although researchers have recently paid more attention workplace social capital (WSC), which was found to associate with health and health-related behaviours, such as smoking, physical activity and medicine adherence. Theoretically, WSC facilitates to solve collective action problems, so WSC may associate with job performance. However, there was sparse evidence on association between WSC and job performance in China context. So building workplace social capital may improve job performance.

Results The prevalence of stress was 54.6%. Stress came mainly from supervisors (63.7%) and was favoured by work situations such as emergency tasks (21.4%), poor organisation of work (20.4%), and Heavy workload (17.8%). More than two-thirds of stressed workers (64%) had psychological distress. Age $p=0.139$, gender $p=0.57$, workplace $p=0.65$, professional seniority $p=0.63$ and the hourly organisation of work $p=0.39$ had no statistically significant impact on the occurrence of stress.

Conclusion Stress is a major psychological risk requiring preventive measures such as listening cells and improved working conditions in human, technical and organisational terms.

626 RELATIONSHIP OF QUALITY OF WORK LIFE WITH DEPRESSION/ANXIETY IN ADMINISTRATIVE STAFF OF AN INSTITUTION OF HIGHER EDUCATION IN MEXICO

R. González-Baltazar*, S.G. León-Cortés, M.I. Contreras-Estrada, G. Hidalgo-Santacruz, J. Hidalgo-González. Public Health Department, University of Guadalajara, Guadalajara, Mexico; Gestalt Institute of Guadalajara, Guadalajara, Mexico

Introduction Currently the Quality of Work Life (QWL) and psychosocial risks are identified as important indicators of health in workers, it is important to carry out studies that can describe the behaviour of them in organisations. The aim was to analyse the relationship between QWL and the presence of symptoms of depression or anxiety in the administrative female employees of a public university in Mexico.

Methods These study was performed with a universe of 6455 employees and a probabilistic sample of 225 people. They all were applied the CVT-GOHISALO and Goldberg's depression and anxiety questionnaires to measure their QWL and the presence of depression or anxiety symptoms. The Cronbach's Alpha of CVT-GOHISALO is 0.9527 and the Goldberg's depression and anxiety scale is 0.89.

Results Only in one of the seven dimensions of CVT-GOHISALO instrument, the highest percentage of satisfaction was of high level, 49.3%, in all other dimensions the highest percentage of satisfaction was of low level. As for the presence of depression symptoms, 20.9% of the employees had them and anxiety symptoms occurred in 59.1%.

In all dimensions, the higher satisfaction with the QWL and the absence of depression or anxiety symptoms were related. As well as low and medium level of satisfaction with the presence of depression or anxiety symptoms. All crosses were statistically significant, with p values for each dimension ranging between 0.000–0.046.

Conclusions To the universe administrative staff, there is a relationship between being satisfied with the QWL and the absence of depression or anxiety symptoms. High satisfaction with QWL, is a protective factor for not having depression or anxiety symptoms. The risk of developing depression or anxiety symptoms, is four times higher for those with low satisfaction level with their QWL than for those who have high satisfaction level.

693 COMBINED EFFECTS OF OVERTIME WORK HOURS AND EXERCISE HABITS ON PSYCHOLOGICAL DISTRESS: A CROSS-SECTIONAL STUDY AMONG JAPANESE WHITE-COLLAR WORKERS

Ayako Hino*, Yumi Wakida, Yusuke Naguchi, Haruka Ido, Akimi Inoue, Kosuke Maafune, Hiyamori Hino. University of Occupational and Environmental Health, Japan, Kitakyushu, Japan; Kitasato University, Sagamihara, Japan

Introduction As symbolised by the word ‘Karoshi’ (death from overwork), the effect of overtime work hours on employees’ physical and mental health is an important issue in Japan. Although there are inconsistent findings regarding the association between overtime work hours and mental health, several studies have found that physical activity has a positive effect on mental health. In this study, we investigated the combined...
