ABSTRACT

Objective Ambient air pollution is associated with ischaemic stroke incidence. However, most of the previous studies used stroke-related hospital admission rather than stroke onset itself. This study aimed to evaluate the relationship between ambient air pollutant exposures and acute ischaemic stroke based on the timing of symptom onset.

Methods A time-stratified, case-crossover analysis was performed among 520 patients who had ischaemic stroke admitted to the Second Hospital of Tianjin Medical University (Tianjin, China) between 1 April 2018 and 31 March 2019 (365 days). Daily air pollutant concentrations of particulate matter with aerodynamic diameter 2.5 µm, particulate matter with aerodynamic diameter 10 µm (PM10), sulfur dioxide, nitrogen dioxide, carbon monoxide and ozone were obtained from fixed-site monitoring stations. We used conditional logistic regression to estimate OR and 95% CI corresponding to an increase in IQR of each air pollutant after adjusting for the effects of temperature and relative humidity.

Results Overall, a higher risk of ischaemic stroke was found between April and September. During this period PM10 was associated with an increased risk of ischaemic stroke (1-day lag: OR=1.49, 95% CI 1.09 to 2.02; 3-day mean: OR=1.58, 95% CI 1.09 to 2.29) among patients between 34 and 70 years old. Positive associations were also observed between PM10 (1-day lag: OR=1.51, 95% CI 1.10 to 2.07; 3-day mean: OR=1.57, 95% CI 1.08 to 2.29), ozone (1-day lag: OR=1.83, 95% CI 1.16 to 2.87; 3-day mean: OR=1.90, 95% CI 1.06 to 3.42) and ischaemic stroke occurrence among those with hyperlipidaemia.

Conclusion Our results suggest that air pollution is associated with a higher risk of ischaemic stroke in younger people or people with hyperlipidemia. These findings still need to be further investigated.

INTRODUCTION

Stroke is a major cause of death and disability worldwide, and stroke burden is particularly high in low-income and middle-income countries.¹ In China, stroke has been the leading cause of death and disability in recent years.² A nationwide population-based study showed that the highest incidence of stroke was found in the northeast region of China, including Tianjin, and ischaemic

Key messages

What is already known about this subject?

- Increasing evidence suggests an association between ambient air pollution and ischaemic stroke.
- Most of the previous studies used stroke-related hospital admission rather than stroke onset itself.

What are the new findings?

- Higher air pollution-associated risk of ischaemic stroke onset was found between April and September.
- During this period, particulate matter with aerodynamic diameter 10 µm (PM10) was associated with an increased risk of ischaemic stroke among patients between 34 and 70 years old.
- PM10 and ozone were associated with an increased risk of ischaemic stroke among those with hyperlipidaemia.

How might this impact on policy or clinical practice in the foreseeable future?

- Certain specific patient subgroups may be at increased risk of air pollution-related ischaemic stroke.
- Improving air quality may help prevent or reduce stroke occurrence, and some simple measures can be taken to reduce individual stroke risk, such as avoiding walking or exercising along traffic roads.

stroke constituted approximately 70% of all incident and prevalent strokes.³ Common risk factors of ischaemic stroke include hypertension, high cholesterol level, smoking and alcohol consumption.^{3–4} Early detection and effective treatment of these modifiable risk factors constitute major current public health measures for the prevention and control of ischaemic stroke.

Many epidemiological and experimental studies have found adverse effects of air pollution on health.⁵ While most early studies focused on respiratory diseases such as asthma, more recent studies showed that short-term or long-term air pollutant exposures contributed to the onset and aggravation

of cerebrovascular diseases, especially of ischaemic stroke.^{5–8} For example, hospital admissions for ischaemic stroke were associated with increased concentrations of ambient air pollutants. Positive associations have been observed for both gaseous air pollutants including sulfur dioxide (SO₂), nitrogen dioxide (NO₂), carbon monoxide (CO), ozone (O₃) and particulate air pollutants, including particulate matter with aerodynamic diameter 10 µm (PM₁₀) and particulate matter with aerodynamic diameter 2.5 µm (PM_{2.5}), in many epidemiological evidence.^{9–13} Based on these and other studies, it is generally believed that hospitalisation data on stroke could better evaluate the temporal sequence between air pollutant exposures and clinical presentation of stroke and increase statistical power.^{8–11} However, some studies have yielded inconsistent results on the association between air pollution and ischaemic stroke occurrence, possibly due to differences in population susceptibility, air pollution levels or components, and meteorological characteristics.^{10–14–16} It should also be pointed out that these risk estimates of air pollutants were based on hospitalisation time rather than the time of ischaemic stroke onset, and studies showed that time to hospital after symptom onset of patients were different in different regions partially due to differences in the knowledge of seeking immediate medical help.¹⁷ These may lead to misclassification of time and influence the evaluation of adverse effects of air pollutants.^{8–18}

In the present study, we recorded the onset time of ischaemic stroke symptoms of each patient to examine the association between short-term air pollutant exposures and onset of ischaemic stroke in a stroke unit in Tianjin, China, using a time-stratified, case-crossover design.

MATERIALS AND METHODS

Clinical data

Data on 525 consecutive patients with a final diagnosis of acute ischaemic stroke confirmed by MRI and/or CT were collected. All patients were admitted to the stroke unit of the Second Hospital of Tianjin Medical University (Tianjin, China) between 1 April 2018 and 31 March 2019. Data were reviewed and recorded by two neurologists and analysed in retrospect. Five of the 525 patients were excluded from the study due to incomplete data, and 520 patients were included in the final analysis. The time of symptom onset was reported by the patients and/or caregivers. For some patients considering thrombolysis, perfusion-weighted imaging was also performed to compare with diffusion-weighted imaging in order to determine ischaemic penumbra and reperfusion time windows. The average distance between where the study participants resided and the hospital was 8 km. The median time to hospital after symptom onset was 15.5 hours (ranging from 30 min to 14 days), with 57 (11.0%) patients admitted within 3 hours after the onset of stroke, 240 (46.2%) within 12 hours and 267 (51.3%) within 24 hours. Nearly half (253, 48.7%) the patients were admitted over 1 day after stroke onset. It would be beneficial to use the time of stroke onset but not time of hospital admission in the study.

Demographic and clinical data included age, sex, medical history (hypertension, diabetes mellitus, hyperlipidaemia, atrial fibrillation, smoking status, alcohol consumption and medication use) and certain laboratory findings, which were obtained by reviewing the medical records of the current stroke admission if the patients were admitted to our hospital for the first time. If the patients were readmitted, past medical records were also reviewed dating back to 2004. No protected health information was collected as data.

Air pollution and meteorological parameters

Air pollution data and meteorological data, including daily mean levels of temperature and relative humidity, between 30 March 2018 and 31 March 2019 (367 days) were provided by the Tianjin Environmental Meteorology Center of Tianjin Meteorological Bureau. Air pollution measurements were the average from the six fixed-site continuous monitoring stations located in the north of the hospital, within 15 km. The air pollutants used in this study included the daily mean levels of PM₁₀, PM_{2.5}, NO₂, CO and O₃. The mean values of air pollutants were calculated over 24-hour periods, except for O₃ which was computed only on 8-hour daytime periods. Daily weather data on temperature and relative humidity were used as adjustment factors in the following multivariable conditional logistic regression models to allow for potential confounding effects of meteorological parameters.^{8–11}

Study design

We used a time-stratified, case-crossover design to study the associations between outdoor air pollution and acute ischaemic stroke occurrence, which is one of the most commonly used methods for studying the health-related effects of air pollution.¹⁹ The study design was an adaptation of a case-control study, in which each case served as its own control. For each case of ischaemic stroke, outdoor air pollution exposure on the case day (the day of stroke onset) was compared with their exposure on referent days. The study referent periods were chosen using a time-stratified design. Three or four referent days were selected from the same day of the week in the same month and the same year as the case day (7, 14, 21 and 28 days before or after the case day). This study design allowed for controlling the effects of time trends, seasonality and day of the week and for matching the time-invariant characteristics of the patients.^{8–20}

Statistical methods

Spearman's correlation tests were used to estimate the associations between air pollutants and meteorological variables. We used conditional logistic regression to estimate the risk effect of each air pollutant after adjusting for meteorological parameters (air temperature and humidity), which was presented by OR and the corresponding 95% CI. The ORs were expressed according to an increase in the IQR of daily mean pollutant levels during the study period. Further stratified analyses were performed to explore whether the associations between air pollutants and ischaemic stroke occurrence were different by season (April–September, October–March), age (34–70 years old, ≥70 years old) and stroke risk factor (hyperlipidaemia) to identify individuals susceptible to the effects of air pollutant exposures. Different time lags for air pollutants were also considered in our analysis, including same-day, 1-day lag and 3-day average. The 3-day average was calculated by the pollutant levels on the same day, 1 day before and 2 days before the ischaemic stroke onset (or the referent days), which could be used to estimate the short-term cumulative effects of air pollution. We also evaluated the differences among risk estimates in the stratified analysis using t-test.^{8–21} P values with a two-tailed significance level less than 0.05 were considered statistically significant. All statistical analyses were performed using SPSS V.20.0 statistics software.²²

RESULTS

A total of 520 patients with acute ischaemia admitted from 1 April 2018 to 31 March 2019 were included in our study. The demographic characteristics of the subjects are shown in [table 1](#).

Environment

Table 1 Demographic characteristics of study subjects

Characteristics	Acute ischaemic stroke (N=520)
Age (mean±SD)	69.9±11.1
34–70 (%)	269 (51.7)
≥70 (%)	251 (48.3)
Gender (%)	
Male	331 (63.7)
Female	189 (36.3)
History of risk factors (%)	
Hypertension	361 (69.4)
Diabetes mellitus	151 (29.0)
Hyperlipidaemia	278 (53.5)
Atrial fibrillation	56 (10.8)
Smoking	181 (34.8)
Alcohol consumption	134 (25.8)
Season* (%)	
Warm (April–September)	281 (54.0)
Cold (October–March)	239 (46.0)

*Time-related variables were based on the time of stroke symptom onset.

The mean age of the subjects was 69.9±11.1 (SD) years old, of whom 51.7% (269) were 34–70 years old. There were a total of 331 (63.7%) male patients and 189 (36.3%) female patients. As regards medical history, there were 361 (69.4%) with hypertension, 151 (29.0%) with diabetes mellitus, 278 (53.5%) with hyperlipidaemia, 56 (10.8%) with atrial fibrillation, 181 (34.8%)

with smoking history and 134 (25.8%) with alcohol consumption history. Among all subjects, 281 (54.0%) ischaemic strokes occurred from April to September and 239 (46.0%) occurred from October to March in the following year during the study period.

Statistical data on air pollutants (PM_{2.5}, PM₁₀, SO₂, CO, NO₂, O₃) and meteorological parameters (temperature, relative humidity) during the study period are summarised in online supplemental appendix table 1. The daily concentrations of air pollutants in Tianjin were much higher than that reported in developed countries.^{11 14} Seasonal Pearson correlations between the daily levels of air pollution and meteorological variables are presented in online supplemental appendix table 2. The daily concentrations of PM_{2.5}, PM₁₀, SO₂, CO and NO₂ were positively associated with each other, and the correlation between PM₁₀ and CO did not reach statistical significance during the warm season. Temperature and humidity were positively associated with each other. O₃, temperature and humidity were positively or negatively associated with other air pollutants (PM_{2.5}, PM₁₀, SO₂, CO and NO₂).

Age differences in the association between air pollution and ischaemic stroke occurrence are shown in table 2. The adjusted OR corresponding to an interquartile increase of 1-day lag PM₁₀ was 1.49 (95% CI 1.09 to 2.02) among patients between 34 and 70 years old from April to September, and a positive association of 3-day average exposure to PM₁₀ was also observed (OR=1.58, 95% CI 1.09 to 2.29). In contrast, there were no significant associations between air pollutant exposures

and acute ischaemic stroke onset among patients ≥ 70 years of age (data not shown). The test for heterogeneity of OR in age-stratified analysis showed that the risk estimates were higher among patients aged 34–70 years old.

In the risk factor-stratified analysis, we observed a significant association between ischaemic stroke occurrence and PM10 levels (1-day lag; OR=1.51, 95% CI 1.10 to 2.07; 3-day mean: OR=1.57, 95% CI 1.08 to 2.29) among patients with hyperlipidaemia from April to September. A significant association was also observed between ischaemic stroke onset and O₃ levels (1-day lag: OR=1.83, 95% CI 1.16 to 2.87; 3-day mean: OR=1.90, 95% CI 1.06 to 3.42) among those with hyperlipidaemia in the same period. In contrast, there were no significant associations between air pollutant exposures and ischaemic stroke occurrence among those without hyperlipidaemia (table 3), whereas the test for heterogeneity of these adjusted ORs among patients with and without hyperlipidaemia showed no difference. Other air pollutants (PM2.5, SO₂, CO, NO₂) were not significantly associated with the occurrence of acute ischaemic stroke in subjects.

DISCUSSION

Our study summarised the associations between air pollutant exposures and acute ischaemic stroke onset in a stroke unit in Tianjin, China, between 1 April 2018 and 31 March 2019. The main findings were the significant association between PM10 exposure and ischaemic stroke occurrence among patients between 34 and 70 years old and the significant association between PM10, O₃ exposure and ischaemic stroke occurrence

among patients with hyperlipidaemia during the warm season (from April to September). The test for heterogeneity by age and hyperlipidaemia showed that risk estimates were higher among younger patients. In our study the risk estimates were based on the timing of symptom onset rather than on the date of hospital admission, which avoided some misclassification of time,¹⁸ and all risk estimates presented here were adjusted for meteorological variables (temperature and relative humidity). Besides, the case-crossover design was effective in controlling for many confounding factors and it was also a suitable method to control for season and day of the week.²⁰

Many studies have reported the associations between air pollution and ischaemic stroke.^{10 16 23} However, other authors did not find these relationships.^{24 25} Our main findings were consistent with several other studies that reported the association between PM10 and O₃ exposure levels and ischaemic stroke occurrence.^{6 8 12} We observed the association between acute ischaemic stroke onset and PM10 levels among patients between 34 and 70 years old from April to September. It is possible that air pollution exposure might vary by age and season. Older people usually spent more time indoors, whereas young-elderly residents spent more time outside during the warm season.^{26 27} Therefore the fixed-site monitoring data could better reflect exposures to outdoor air pollutants on warm days among the younger patients. In contrast, the risk estimates for the cold season may be underestimated. Weather factors could also modify the effects of air pollution. Some studies found that ischaemic stroke hospitalisations were associated with air pollutants

only on warm days.^{11 28} High temperatures were demonstrated to cause vascular endothelial dysfunction and increased platelet, cholesterol and haemoconcentration, thereby contributing to the occurrence of ischaemic stroke.²⁹ During the study period, there were higher levels of O₃ during the warm season in Tianjin, and further stratified analysis showed that both O₃ and PM10 exposures were positively associated with ischaemic stroke onset among patients with hyperlipidaemia on warm days. The results suggested that people with hyperlipidaemia might be more susceptible to the harmful effects of O₃ exposure than those with normal plasma lipid.

Several plausible biological pathways may be involved in the adverse health effects of air pollutants. Both gaseous air pollutants and particulate matter (PM) had adverse effects on health; however, many evidence showed that the most serious effects were related to PM, including PM10.³⁰ These particles contain various toxic substances, and in metropolitan areas most PMs are anthropogenic, mainly originating from burning of fossil fuels.³¹ PM10 exposure could promote platelet activation, thereby contributing to thrombosis and coagulation.⁶ Findings in animal models also provided experimental evidence that PM10 exposure was related to inflammatory response by inducing the release of plasma proinflammatory cytokines, which may be associated with endothelial dysfunction and severity of brain ischaemia injury.³² However, more studies related to the effects of PM on humans and animals are needed to reveal the underlying mechanisms due to the complex composition of these particles. O₃ is one of the most harmful gaseous air pollutants and is a powerful oxidising agent. O₃ inhalation can promote increased oxidative stress and mitochondrial DNA damage, which could also lead to systemic inflammatory responses.³³ The systemic inflammatory responses caused by PM10 and O₃ exposure are also related to acceleration of atherosclerosis, playing a role in the development and progression of ischaemic stroke.^{34 35} People with hyperlipidaemia may have higher risk of atherosclerosis and may be more vulnerable to PM10 and O₃ exposure.

The high pathogenic complexity of ischaemic stroke should be considered when interpreting our present results since it could lead to underestimation of the environmental effects. A Korean study suggested that short-term exposure to PM10 and SO₂ was especially associated with cardioembolic stroke rather than large artery atherosclerosis and other non-cardioembolic strokes.³⁶ However, other studies showed that PM10, PM2.5 and O₃ exposure was associated with large artery atherosclerotic strokes, small vessel occlusions and lacunar strokes rather than cardioembolic strokes.^{12 13 37 38} So air pollutants could variably affect different pathophysiological pathways, and the effect of air pollution on ischaemic stroke may differ among different ischaemic stroke subtypes, therefore leading to different outcomes. Moreover, geographical factors, air quantity monitoring stations, study design, adjusted confounding factors and some other factors varied in different works.

The strengths of this study included the validated stroke onset time, comprehensive medical data and the time-stratified cross-over design. However, there were still some limitations. First, the study population was from a single institute only, which could limit the generalisability of the results. A larger multicentre study including more patients would better reflect the effects of air pollution on ischaemic stroke occurrence. Second, we did not analyse the effects of air pollution by ischaemic stroke subtype due to the small sample size. More efforts are needed since air pollutants may affect related pathophysiological pathways in various degrees. Third, average air pollution information was collected from fixed-site monitoring stations, and there would

be exposure misclassification if air pollution at fixed sites is measured as individual exposure. So there may be some biases in our risk estimates, and the absence of associations with some pollutants in the study might have resulted from methodological disadvantages. Individual-level exposure measurements were considered to be superior when evaluating the health effects of outdoor air pollution. In the present study, most of the patients resided in urban Tianjin, and the average air pollution level in the urban area could reflect the average exposure level to some extent.

In conclusion, our study indicated that short-term outdoor air pollutant exposure was associated with ischaemic stroke occurrence in Tianjin. These associations were more evident during warm days. Associations between stroke occurrence and PM10 and O₃ pollution exposure among subjects between 34 and 70 years old or subjects with hyperlipidaemia from April to September suggested that specific patient subgroups may be at increased risk of air pollution-related ischaemic stroke. Improving air quality may help prevent or reduce stroke occurrence, and some simple measures can be taken to reduce individual stroke risk, such as avoiding walking or exercising along traffic roads. Inflammatory responses may be involved in this process through plaque instability; however, the specific pathophysiological mechanism is still unclear. Further studies are needed to confirm our findings.

Contributors XQ collected the data, performed the statistical analysis and drafted the manuscript. ZW, XG and XX collected the data and revised the manuscript. JX, GJ and YG collected the clinical data and revised the manuscript. SH, QY, ZC and XW collected the meteorological and air pollution data and revised the manuscript. LW revised the manuscript. SXL designed the study and revised the manuscript. XL designed the study, double-checked the statistical analysis and revised the manuscript.
