respiratory symptoms. However, quantitative exposures to these products are not well-characterized. The objective of this study was to characterize exposures to cleaning and disinfecting chemicals in healthcare occupations.

Methods Exposure assessments were conducted at five hospitals targeted 14 healthcare occupations. Mobile-area and personal real-time and time-integrated air monitoring was conducted for volatile organic compounds (VOCs), and 14 specific VOCs were quantified, including total VOCs (TVOCs). Quaternary ammonium compounds (QACs) were quantified at one hospital. Exposure data were summarized by occupation and geometric means (GMs) and geometric standard deviations (GSDs) were calculated. GM exposure estimates for product-application tasks were obtained from linear regression models.

Results The GMs for TVOCs were highest among nursing assistants, licensed practical nurses, and medical equipment preparers (range: 4367–2142 ppb), followed by respiratory therapists, pharmacy technicians, registered nurses, housekeepers, floor strippers/waxers, and dental assistants (range: 2120–1565 ppb); GSDs varied from 1.06 to 9.01. GMs for selected VOCs were: ethanol (1.54–2594 ppb), acetone (18.5–70.6 ppb), chloroform (0.09–0.37 ppb), α-pinene (0.04–0.19 ppb), and d-limonene (0.12–4.23 ppb). Real-time TVOC GMs were the highest for the product-application tasks of using skin wipes containing QACs, using enzymatic cleaners, using glass-cleaning products, cleaning instruments with high-level disinfectants, and using detergents to clean surfaces (2091–4104 ppb). Specific VOC levels were strongly associated with product-application tasks; using products containing bleach or QACs predicted levels of chloroform and d-limonene, respectively. Concentrations of QACs were low in short-duration tasks; using products containing bleach or QACs predicted levels of chloroform and d-limonene, respectively.抱团式 GMs for TVOCs varied by occupation and tasks. These estimates can be used to generate a job-task exposure matrix for use in epidemiologic studies.

S-73 ARE EARLY WORKING LIFE PATTERNS RELATED TO THE COURSE OF FUTURE SICKNESS ABSENCE DUE TO COMMON MENTAL DISORDERS?

1Amaya Ayala-Garcia, Laura Serra, Monica Ubalde-Lopez. 1Universitat Pompeu Fabra, Spain 10.1136/OEM-2021-EPI.400

Introduction In recent decades, the labour market has evolved into temporary employment, part-time work, and long-term unemployment, especially affecting young people and women. Transitions between states during working life could affect mental health.

Objectives To assess the relationship between early working life (EWL) patterns and the future course of sickness absence (SA) due to mental disorders.

Methods Cohort study of a working sample between 18 and 28 years of age, residents in Catalonia, with at least one episode of SA due to a mental disorder between 2012 and 2014. Reconstruction of individual working life trajectories previous to the SA was carried out by sequence analysis based on four work-related states (permanent, temporary contract, unemployment and without social security coverage). By optimal matching, patterns were identified out of clustering similar working trajectories. Identification of SA trajectories were made by latent class growth modelling analysis. Adjusted multinomial logistic regression models were applied to assess the relationship between early working life patterns and SA trajectories.

Results Among men, fluctuating (aOR 1.25 [95% CI: 0.57–2.74]) or delayed (aOR 1.79 [95% CI: 0.59–5.41]) entry into the labour market showed a trend towards a middle stable accumulation of SA days. In women, an increasing permanent and fluctuating employment pattern (aOR 2.41 [95% CI: 1.01–5.75]) at the beginning of their EWL was related to a decreased accumulation of future days on SA due to mental disorders (aOR 2.08 [95% CI: 1.18–3.66]) rather than to a low stable trajectory.

Conclusions An unstable early working life built on a high number of transitions between temporary contracts, unemployment and lack of social security coverage states is related to a future worse SA course due to mental diagnosis.
