THE IMPACT OF WORKPLACE SOCIAL SUPPORT ON MENTAL HEALTH FUNCTIONING: A COHORT STUDY OF THE WORKFORCE IN STOCKHOLM COUNTY, SWEDEN

Kathryn Badarin, Andreas Lundin, Yvonne Forsell. Karolinska Institutet, Sweden

Introduction The burden of mental illness is pervasive. Improved methods for early detection of mental ill-health and comprehensive understandings of factors associated with declining mental health are needed. Workplace social support is an important factor for addressing employee’s mental health. However, only a few studies have explored how workplace social support impacts on mental health from a functional perspective.

Objectives To investigate the prevalence of limited Mental Health Functioning (MHF) among Swedish workers and the association between workplace social support and MHF.

Methods This cohort study used a sample of 4979 employees from Stockholm County who responded to population-based questionnaires in 2000 and 2002. Two subsamples were explored: workers without baseline limitations in MHF (n=2844) and workers with baseline limitations in MHF (n=2135). Exposure to workplace social support was estimated using the Swedish Demand-Control-Support Questionnaire. Follow-up data on MHF were taken from the World Health Organisation’s Brief Disability Questionnaire. Multinomial regression analysis generated odds ratios (OR) with 95% confidence intervals (CI95%) adjusting for age, sex, education, socio-economic classification, cohabitation and social support outside the workplace.

Results In total, 43% (37% moderate and 6% severe) of workers had limited MHF at baseline. A higher level of workplace social support was associated with a reduced likelihood of moderate functional limitations (AOR 0.92 95%CI, 0.89–0.95) or severe functional limitations (AOR 0.87 95%CI, 0.80,0.94) two years later. Among workers with pre-existing functional limitations, increased workplace social support was associated with improved MHF at follow-up (AOR 1.08 95% CI, 1.05, 1.12).

Conclusions Limited MHF was prevalent among workers. We observed a protective relationship between increased workplace social support and limited MHF. Increased social support was also associated with improved MHF among workers with limited MHF. Interventions that increase workplace social support might protect against a deterioration in MHF and improve MHF among workers with pre-existing limitations.

WORKPLACE VIOLENCE AMONG WOMEN IN INDUSTRIAL FACTORIES

Alireza Dehdashti. Medical Sciences University of Semnan, Islamic Republic of Iran

Introduction Workplace violence concerns a form of aggression encompassing behaviors that are intended to cause physical and mental harm. While studies reported violence is a major and increasing concern for the work environment in all countries, violence against female workers in the industrial sector has received less attention.

Objectives This study investigated the prevalence of various types of violence and associated factors among female workers in the industrial sector.

Methods This descriptive survey was conducted in eleven industrial sites in Iran. Cross-sectional data were collected by a 78-item questionnaire from 817 female workers recruited through workplace safety and wellbeing units inside the factories. The study measured three types of violence involving physical attacks, verbal threats, and sexual aggressions. Multiple logistic regression analyses were used to analyze how demographic characteristics and occupational factors were associated with women’s perceived violence in work life.

Results About half of the participants reported having experienced at least one type of violence. The prevalence rates of verbal aggression, sexual harassment, and physical violence were 52.5%, 12% and 11.5%, respectively. Single female workers (adjusted odds ratio [AOR] =2.06, 95% CI= 1.09–4.27), and age older than 35 years were
(AOR = 2.37, 95% CI = 1.26–2.93) each significantly related to increased odds of verbal violence. Short duration of employment (<five years) was the most strongly associated factor for sexual harassment (AOR = 2.82, 95% CI = 1.7–2.94). Working the night shift was significantly associated with encountering verbal violence (AOR = 2.79, 95% CI = 1.69–3.06).

Conclusion The findings of this study highlighted occupational violence and the need for an awareness of violence against female workers in industrial plants. The high prevalence of violence suggests that management in industrial workplaces should invest time and resources in addressing violence. Providing reporting procedure and training programs are recommended in dealing with workplace violence risk.

Introduction Mental health problems cause a considerable burden of disease in adolescents, with potential negative consequences on employment later in life. Earlier, five trajectories of internalising and externalising problems (high-stable, moderate-high, decreasing, moderate-low, low-stable) among adolescents from 11 to 19 years were identified and a relationship with employment status at age 19 was found. However, at age 19, many participants were still in education.

Objectives This study aims to examine associations of trajectory membership with having paid work and type of employment contract in young adults at age 26.

Methods Fifteen-year follow-up data of the longitudinal TRacking Adolescents’ Individual Lives Survey (TRAILS) cohort study (N=1711) were used. Logistic regression analyses were applied to examine associations of trajectory membership of internalising and externalising problems with having paid work and type of employment contract at age 26. The analyses were stepwise adjusted for sex, intelligence, parental education, family composition, physical health, negative life events and mental health comorbidity, all measured at age 11.

Results For internalising problems, the high-stable (adjusted OR: 2.19; 95% CI: 1.17–4.11) and moderate-high (adjusted OR: 1.75; 95% CI: 1.14–2.69) trajectories were strongly associated with not having paid work, compared to the low-stable trajectory. No associations were found between the trajectories of externalising problems and having paid work. For both internalising and externalising trajectories, no associations were found between trajectory membership and having a permanent or temporary employment contract.

Conclusion This study expands current knowledge about the impact of internalising problems on employment of young adults. To prevent the effects of mental health problems on work, a life course perspective is needed taking into account the development of mental health problems in childhood and adolescence. In the transition from school to work, integrating youth- and occupational healthcare may be key to prevent negative employment outcomes due to internalising problems.

Preliminary evidence suggests that higher winter depression prevalence at temperate latitudes has been attributed to low daylight levels. Daytime light exposure varies across jobs.

Objectives In a nationwide study, we examined occupational daytime light exposure levels and risk of initiating antidepressant treatment among men and women.
