Classification of outcomes for each intervention target

Universal interventions

Critical:

- Mental health symptoms and disorders
- Positive mental health
- Quality of life and functioning
- Work-related outcomes

Important:

- Adverse effects
- Substance use
- Suicide

Selective and Indicated interventions

Critical:

- Mental health symptoms and disorders
- Positive mental health
- Quality of life and functioning
- Substance use
- Suicide
- Work-related outcomes

Important:

- Adverse effects

AMSTAR-2 Quality Assessment

The quality of the included meta-analyses was assessed using AMSTAR-2 (Shea et al., 2017). AMSTAR-2 critically appraises core methodological characteristics of systematic reviews including (1) adequate definition of participants, intervention, comparator, outcome (i.e., PICO), (2) methods were established before the conduct of the review, (3) justification for the study designs, (4) comprehensiveness of the search, (5) study selection and (6) data extraction conducted by two reviewers, (7) list of excluded studies with reasons, (8) detailed description of included studies, (9) adequate methods for Risk of bias assessment (RoB), (10) investigation of sources of funding, (11) appropriate methods for pooling, (12) examination of the impact of RoB on the outcomes, (13) discussion of the impact of RoB in the interpretation of results, (14) adequate exploration of heterogeneity, (15) assessment of publication bias, (16) reporting potential conflict of interests for the review. Items 1, 3, 5, 6, 10, 11, 12, 13, 14, 15 and 16 were rated as positive (Yes) or negative (No), and Items 2, 4, 7, 8, and 9 also included a partially positive answer (Partial Yes). Each item was rated by two independent reviewers (CM, AA), and disagreements were solved by discussion or consultation with a third reviewer (PC).

GRADE Assessment

Further details regarding the ratings of each of the GRADE main factors:

Risk of bias (RoB): We extracted the RoB ratings from the individual studies included in the meta-analyses (when available). We calculated the percentage of trials rated at low, high, and unclear risk of bias. Based on this information, and in order to take consistent decisions across the available evidence, we rated the RoB GRADE item using a decision tree (Figure 1).

Inconsistency: We judged inconsistency by examining heterogeneity statistics (I^2 , which indicates the percentage of heterogeneity between effect sizes). Whenever possible, we computed the 95% CI of I^2 and used it in our judgements. We judged inconsistency as serious when I^2 was over than 75% and its 95% CI substantially overlapped with the category of considerable heterogeneity (above 75%). Substantial overlap was estimated with the median of the 95% CI. When the 95% CI could not be calculated, we rated it as serious if heterogeneity was larger than 50% (category of substantial heterogeneity). When I^2 was not reported and could not be calculated, we rated it as serious.

Indirectness: Direct evidence is derived from research that directly compares the interventions which we are interested in, delivered to the participants in which we are interested, and that measures the outcomes important to patients. We rated for each particular comparison how indirect was the reviewed evidence in terms of population, intervention, and outcomes.

Imprecision: We rated this item based on a standard power calculation (α 0.05 and β 0.20) for detecting an effect size of 0.2, which requires a sample size of 400 participants in total. We judged as serious all analyses including less than 400 participants. Analyses including less than 100 participants were rated as very serious. We rated it as serious when the number of participants included in the analyses was not available.

Other considerations: For this item we focused on publication bias. We rated it as serious when there was evidence for publication bias in the meta-analyses, based on statistical tests. However, we did not downgrade the evidence when the meta-analyses did not investigate it.

- No data available for risk of bias → serious
- When majority ($\geq 60\%$) of trials are low risk → not serious
- When low risk is between 50-59%:
 - High risk $< 25\%$ → not serious
 - High risk $\geq 25\%$ → serious
- When majority ($\geq 60\%$) is high risk → very serious
- When high risk is between 50-59%:
 - Low risk $< 25\%$ → very serious
 - Low risk $\geq 25\%$ → serious
- When majority is unclear risk ($\geq 60\%$) → serious
- When unclear risk is between 50-59%:
 - High risk $< 25\%$ → not serious
 - High risk $\geq 25\%$ → serious
- If both unclear/low risk are $< 60\%$:
 - High risk $< 25\%$ → not serious
 - High risk $\geq 25\%$ → serious

Figure 1. Developed decision tree for the assessment of risk of bias in GRADE.
